The present work treating of veterinary bacteriology by the bacteriologist to the Iowa agricultural station is a clear, business-like, well-arranged, and accurate presentation of its subject, but will appeal more especially to those whose ideal of education is teaching rather than learning. The volume is based on a course of lectures given to students of veterinary medicine in the Iowa State College, and it casts a curious sidelight on the general education that it should be considered necessary to give the singular forms of such words as septa, hyphæ, exanthemata, and so on.

The author states his aim to be "to put in usable form that fund of knowledge concerning bacteriology which the student of veterinary medicine should master." The matter is divided into six sections, of which the first two deal with general considerations of morphology, classification, cultivation and demonstration. As the author disclaims the intention of making his work a text-book of pathology or a manual of laboratory practice, this disarms criticism of the somewhat sketchy but possibly sufficient treatment of these sections. The third section, in which immunity and the constitution of the various antibodies are discussed, is a clear and praiseworthy exposition of the subject.

The fourth and longest section deals with the pathogenic micro-organisms, exclusive of the protozoa. It is natural to look here for a treatment somewhat different from that adopted in the ordinary medical text-book. It must be confessed, however, that the work would serve almost equally well for the medical as for the veterinary student. The organisms dealt with are for the most part those found in medical text-books, and in a few cases organisms special to man are included. This is in part no doubt due to the fact that it is on work done on human disease that many of the fundamental ideas on immunity, treatment, and diagnosis

are based. We miss, however, any insistence on matters important to the veterinary surgeon in dealing with food-poisoning epidemics, the relation of diphtheria and tubercle to milk, the connexion of human ringworm with similar diseases in animals, and other like matters. Water examination and purification are briefly treated, but there is no section on milk. The statement that T.R. has not come into use should be reconsidered.

The fifth section concerns the pathogenic protozoa, and is of great importance in view of the number and serious character of the animal diseases caused by protozoa, and the frequency with which the animal acts as a carrier for human parasites. The final section deals with diseases produced by ultramicroscopic organisms. A short bibliographical index is appended. The book is well illustrated with blocks, the majority of which are from the Atlas of Fraenkel and Pfeiffer. It is well printed and of good appearance.

Manual of Psychiatry. By J. ROGUES DE FURSAC, M.D. Translated and edited by A. J. ROSANOFF, M.D. New York: John Wiley and Sons. 1911. Pp. 484. Price $2 50.

THIS book is the third American edition translated from the third French edition. The new matter which has been introduced has enlarged the volume by about 80 pages. Much of the fresh material is from the pen of the editor, and includes sections upon the Mendelian hypothesis, psychotherapy, chemical tests for certain abnormal substances in the cerebro-spinal fluid, and a description of the Wassermann reaction. As a handy account of the findings of the psychiatry of to-day the book may be commended. The first part is devoted to general psychiatry, and contains an account of the various symptoms that may be met with, while the second part is composed of an account of the aggregations of symptoms forming the recognised syndromes. It has too often happened in the past that the somatic phenomena which are associated with mental disorder have been disregarded, but in the present work their significance is accentuated. Treatment is so often vitiated by ignoring the physical illness or debility which accompanies mental disorder that it becomes highly desirable that stress should be laid upon the bodily state. The author, while admitting the existence of dementia præcox as a clinical entity, criticises the name. He points out that the dementia present is often very slight in amount and selective in character, so that certain particular faculties may be affected while others are left intact. So far as the adjective "præcox" is concerned, it is certainly not the rule that the disease always runs a rapid course ending in dementia, or that it necessarily occurs at an early age, and there is but little doubt that the name given to the disease has hindered the acceptance of the conception it covers. The description of the Mendelian hypothesis, taken from another work of the editor, is adequate and good.

Handbuch der Vergleichenden Physiologie. Herausgegeben von HANS WINTERSTEIN. 16. Lieferung. Band IV.: *Physiologie der Reizaufnahme, Reizleitung, und Reizbeantwortung.* Erste Hälfte. Bogen 21–30. Jena: Gustav Fischer. 1911. Pp. 321–480. Price 5 marks.

THIS part winds up what Dr. Baglioni has to say about the physiology of the nervous system of insects.[1] Substantially it deals with the physiology of the nervous system of vertebrates, beginning with fishes and, of course, with amphioxus, and then passes on to cartilaginous and osseous fishes. To the average reader the account of the pigmentary or colour changes in soles and other flat fish, a study begun by Pouchet and recently brought into popular prominence by the work of Dr. Francis Ward, of Ipswich, will prove very attractive. The velocity of conduction in the nerves of fish, frog, and man is noted, but the chief interest centres round the effects produced by removal of the cerebral centres, on the one hand, and stimulation of these centres on the other, in different animals. Naturally the author draws largely on the well-known observations on fish of Steiner and of Bethe. The frog, as a typical amphibian, is next considered, and the work of Goltz on the effects of removal of certain parts of the brain is admirably summarised (pp. 352–413), and so is that of Steiner and Schrader on the same subject, as well as the later work of Verworn, the worthy successor of Pflüger in Bonn, on tonic reflexes.

The reptilia (pp. 413–423) are next dealt with, and the work of G. Fano on the results of removal of the brain in the tortoise is summarised. As to snakes, we must go back to the excellent work of Tiegel on the spinal cord, and to that of Luchsinger. The author carries us *gradatim* and historically to Biedermann's work on the chameleon—a subject initiated as well as illustrated by Brücke. Birds and the functions of the "brain centres" and related subjects occupy pp. 424–437, and just at the end Langley's work on the sympathetic system of birds and on the muscles which move the feathers is referred to (1904). This constitutes the fourth chapter.

The fifth chapter deals with mammals, but according to the author the subject is so well treated in the text-books—especially in regard to the nervous system of the dog and ape and localisation—that he confines himself to what is known as to the physiology of the nervous system of bats (pp. 438–440), and then in Part II. of the same chapter (pp. 441–450) he deals with the other mammals. The work of Sherrington should have found a larger place than it occupies.

The bibliography is long, but not complete. Some names are omitted that ought to have been included. The last few pages are occupied by the beginning of the article on Tropisms by Professor Jacques Loeb.

[1] See review of earlier section, THE LANCET, Sept. 16th, 1911, p. 830.

LIBRARY TABLE.

Tropical Hygiene for Anglo-Indians and Indians. By the Honourable Surgeon-General C. P. LUKIS, M.D. Lond., C.S.I., and Major R. J. BLACKHAM, R.A.M.C. Calcutta: Thacker, Spink, and Co. London: W. Thacker and Co. 1911. Price 4*s.* 6*d.* net.—This book has been compiled as a manual of instruction for the senior certificate in home hygiene of the St. John Ambulance Association in India, and is divided into ten chapters corresponding with the ten lectures that form the authorised syllabus of instruction. The first is entitled the Communicable Diseases of the Tropics, and deals shortly with cholera, dysentery, plague, enteric fever, and tuberculosis. In the second chapter malaria is treated somewhat fully, and mention is made of kala-azar and sand-fly fever. Then follow chapters on air, water, food, clothing, houses, and refuse disposal as regards the conditions of hot climates. A full description of tropical insects is given in relation to disease, with numerous illustrations, and finally disinfection is treated briefly but sufficiently. The book is written in a popular style, and the facts are made as easy of comprehension by readers untrained in medical science as the nature of the case admits. The authors advise that cholera stools should be burned or buried; it is not always easy to burn a cholera stool; boiling is the safest and easiest method of disposal if heat is available. Neither in the preventive precautions against cholera or dysentery is any mention made of protecting the abdominal viscera by wearing a flannel belt; this seems to us a real omission. On p. 10 the authors state that in enteric fever the urine and expectoration are equally dangerous with the stools in

spreading infection; this is certainly quite true for the urine, but can hardly be maintained in reference to the sputum. The information as to malaria causation and prevention are excellent; the authors have put it very tersely in the sentence: "In a general way it may be said that when malarial fever occurs in Europeans, the latter have acquired it from mosquitoes that have previously bitten an infected Indian, who is more often than not one of his [their] own servants or a child in the compound." The authors rightly say that the natives of India have not yet realised the importance of fresh air; but the number who die annually in India is not 37,000, as stated on p. 45, but 37 per 1000; the death-rate is now rather lower, and, of course, the slip is obvious. The statement that in a certain hospital, after the ventilation was improved, the deaths were "nine-tenths less than before," which means a reduction of mortality to one-tenth of that previously existing, is significant. Is not allowance of two pints of liquid daily, over and above moisture in food, in temperate climates (p. 47) very small, and would it be generally accepted? We are glad to note that stress is laid on the fact that no filters of the Pasteur-Chamberland or Berkefeld type can be useful in the tropics unless a rough clarifier is attached. More stress might perhaps have been laid on the dangers of milk in tropical countries. Milk pasteurisation might have been described, as it is extremely valuable for use in India. The account of insect parasites is excellent and fully illustrated. We have pointed out several small matters of detail which can readily be corrected. Of the manual as a whole we can speak most favourably. It contains a large amount of information, clearly expressed, and (with the trifling emendations suggested) will admirably serve the purpose for which it has been compiled.

The Canada Year Book, 1910. Second Series. Ottawa: C. H. Parmelee.—In this Year Book, which, though dealing with 1910, and having its preface dated July, 1911, has only just put in a belated appearance, there is a large amount of useful information with regard to Canada, consisting principally of statistics relating to population, agriculture, and manufactures. The population statistics are compiled from the census reports, and give figures for the two decennial periods 1871 to 1901 with regard to such matters as sex, conjugal state, birthplace, race, and religion. The mortality rates for the periods named are also given, as well as the school attendance figures and the status of education. The details with regard to imports and exports have been made more complete than those of previous editions of the book, and there is a brief account of the chief events of the year 1910.

MISCELLANEOUS VOLUMES.

MANY books of varied character, some of them having little connexion with matters medical, save the very remote one that all things which exercise on man even the slightest influence are to that extent the concern of medical science, lie on the editor's table.

The Climate of the Continent of Africa, by ALEXANDER KNOX, B.A. Cantab., F.R.G.S. (Cambridge University Press, 1911. Price 21*s.*), is really a scientific treatise of importance as is evidenced by the fact of the assistance given to the author by the Royal Geographical Society and several other British and foreign geographical, meteorological, and other societies, and by various Government officials and distinguished travellers. Though obviously a marvel of painstaking research, the subject is one that would hardly justify the elaborate pains and the space in our columns necessary to do justice to the book.——The translation of the *Oedipus* of Sophocles into English rhyming verse by Mr. GILBERT MURRAY, LL.D., D.Litt., Regius Professor of Greek in the University of Oxford (London: G. Allen and Sons. 1911. Price, net, paper, 1*s.*; cloth, 2*s.*), has a special interest just now, owing to the production of that great drama in London under the direction of Max Reinhardt, who has already scored a brilliant success with the play in Berlin. The *Oedipus* is pre-eminently a human play, and it is because of its sustained but gradual unfolding of the plot with increasing grip up to the final catastrophe that it will always take a foremost rank in tragedy. Professor Murray's translation is scholarly, especially in the fact that though fairly close to the original it is no mere rendering of words for words, but it carries the reader with it into the original atmosphere of the play.——The *Divine Comedy* has been translated many times into English with varying success. The latest attempt is particularly ambitious because the translator, Mr. C. E. Wheeler, has essayed to render Dante's immortal trilogy into rhymed verse, keeping the triple rhythm of the original. This new translation is published in three convenient little volumes, entitled respectively "Hell," "Purgatory," and "Paradise" (London: J. M. Dent and Sons. 1911. Price 2*s.* 6*d.* each, net). In spite of weaknesses (how should it be otherwise?) Mr. Wheeler's version deserves a place among the better English translations of the *Divine Comedy*, while its size and price place it within the reach of many ordinary readers to whom the standard editions are somewhat inaccessible. The translator acknowledges his debt to the Temple edition, from which he has taken the arguments and notes. It is almost impossible to preserve a uniform level of achievement in a translation which undertakes the double task of reproducing the original meaning, style, and rhythm, and yet of preserving the best features of rhymed English verse. This is not the place to pick out either good lines or bad lines—though we have found many of each—and we will only say that every lover of Dante who appreciates careful, reverent translation and dexterous versification should read Mr. Wheeler's rendering.——In *The King to His People* (London: Williams and Norgate. 1911. Price 5*s.* net) are collected the speeches and messages of His Majesty King George V. as Prince and Sovereign. Naturally they touch on a wide variety of subjects, with only a few of which is the medical profession even indirectly interested. Still, even so, there are subjects, such as the Opening of the National Physical Laboratory, the London Orphan Asylum, The Housing Problem, The Doctor, A Century of Medicine, Fighting the White Plague, Cancer Research, "Bart.'s," The Rule of Science, Homeless Children, Hospital Problems, Boy Scouts, and others, which manifest His Majesty's deeply sympathetic feeling towards the importance of medical affairs in their close relation with human welfare at large.——The high place of Darwin in modern science is, we imagine, too well established to be upset by Mr. Herbert Morse's philosophical and critical study of Darwin's theory of "Natural Selection," in his book, *Where Do We Come From? Is Darwin Correct?* (London: Kegan Paul, Trench, Trübner, and Co., Limited. 1911. Price 7*s.* 6*d.* net). Doubtless much has been discovered since Darwin's time which he would willingly have taken into consideration had the knowledge been then available, and in the light of which he would doubtless have made such modifications in his own views as seemed necessary. The whole history of his life shows that he was far too real a scientist to lay down his theories first and then endeavour to make facts square with them. He was first of all a patient observer, accumulating and classifying facts, then drawing his inferences and establishing his theories as they appeared to emerge from his ordered data. To say that all his conclusions were final would be to claim for him omniscience. Finality is not to be expected in science. Conclusions can hold only until new data appear, which, being unknown or even undreamed of when the conclusions were drawn, could not be taken into account. Science

recognises a process of repeated stocktaking and re-adjustment.

Turning to more strictly medical books, we find a thesis for the Doctorate in Medicine of the University of Venezuela, by P. F. ARREAZA CALATRAVA, on *La Peste en Caracas: Epidemias de 1908-1909-1910* (Caracas: Tipografia Americana. 1911), which discusses its subject with praiseworthy thoroughness from the points of view of the epidemiological data, the etiology and pathological anatomy, the protogenesis and pathogenesis, the clinical forms, the diagnosis and prognosis, the treatment, and concludes with a series of clinical observations and temperature charts. In regard to the treatment of bubonic plague, the author holds that extirpation of the buboes, so gratuitously decried by some and so over enthusiastically praised by others, will undoubtedly become generally accepted as a rational and scientific treatment when its indications can be made more precise by a tranquil and impartial analysis of conditions. The tables of cases in which this operation was performed seem to lend some colour to his expectations.——From epidemic disease to public health is a natural transition, and the *Pocket Notes and Remembrancer for Sanitary Inspectors and all engaged in Public Health Work*, by J. T. COWDEROY, Chief Sanitary Inspector to the Borough of Kidderminster, now in its fourth edition (London: The Sanitary Publishing Co., Limited. 1912. Price 2*s.* net) affords a considerable amount of material that would be useful to those for whom the little book is especially written and also to many practitioners, especially in country districts. It consists of summaries of the various Acts relating to Public Health, Housing of the Working Classes, River Pollution, Infectious Diseases, Sale of Food and Drugs, Sanitary Defects and Nuisances, Slaughter-houses, Canal Boats, Shop Hours, Factories and Workshops, Burial Grounds, and Meat Inspection. There are sections on microscopic stains and methods of staining and on methods of disinfecting clothing, cesspool requirements, technical terms in use in the different professions and trades that come into contact with sanitary work, the Housing and Town Planning Act, and so forth.——In *Health Readings*, by C. J. THOMAS, M.B., B.Sc. Lond., D.P.H. (London: Methuen and Co., Limited. 1911. Price 1*s.* 6*d.*), we begin at the very beginning of the subject. This is "a book all about the body and the things which do it harm and the ways which keep it well," written in the colloquial style, midway between the didactic and the catechetical, calculated to catch the interest of juvenile readers and carry them along in the study of their own natures and physical organisms. Starting with the difference between living and dead things the body is first described in admirable simplicity, and the effect on it of clothing, food, fresh air, housing, cleanliness, exercise, rest, and sleep are so discussed as to impart without any special effort of learning a considerable amount of physiological knowledge. A few simple instructions for the more ordinary accidents conclude the book.——Both sport and the Riviera are mentally associated with health and hygiene, and in *Sport on the Rivieras*, edited by EUSTACE REYNOLDS BALL, F.R.G.S., and C. A. PAYTON, M.V.O. (London: 27, Chancery-lane. 1911. Price 2*s.* 6*d.*), we find an excellent attempt to deal with popular winter resorts from the purely recreative side. Golf, lawn tennis, motoring, cycling, river-, lake-, and sea-fishing are discoursed of in a way to attract the attention of many who have hitherto regarded the Riviera as a collection of places for the invalid or the fashionable world. The list of writers includes, besides the editors, Arthur S. Browne, J. D. E. Loveland, C. N. Williamson, Captain E. D. Miller, D.S.O., A. W. Rumney, H. R. Reynolds, M.A., and "Sarcelle," of *The Field*, all of them authorities in their special fields.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. V., No. 18. January, 1912. Oxford: At the Clarendon Press. Subscription price, 25*s.* per annum. Single numbers, 8*s.* 6*d.* net each.—The contents of this number are: 1. The Adrenal Cortex, its Rests and Tumours; its Relation to other Ductless Glands, and Especially to Sex, by Ernest E. Glynn. The objects of this paper are described as being to classify and describe the commoner adrenal tumours upon a combined clinical and histogenetic basis; to draw attention to the relation between the adrenal cortex and other ductless glands, and especially to its relation to sex characters; and to present new reasons against the hypothesis that renal hypernephromata are derived from adrenal rests. The adrenal cortex is regarded as being specially connected with growth and sex characters; the medulla with blood pressure. Adrenal hypernephromata are associated with sex abnormalities, almost invariably in children, usually in adult females before the menopause, but apparently never in adult females after the menopause nor in adult males. Rests from the adrenal cortex are common in certain localities, especially in infancy, except in the kidney. Various reasons against the hypothesis of Grawitz that the tumours called renal hypernephromata arise from remnants of adrenal cortex are given. The paper has a long list of references and is illustrated by a plate. 2. The Antigen (Vaccine) Treatment of Enteric Fever, by F. J. Sadler. The term vaccine, though generally employed, is considered inappropriate and is used under protest, the alternative of antigen treatment being suggested. Details of a number of observations are given, and the general conclusions arrived at are that the treatment of enteric fever by vaccines makes average cases mild, severe cases average, and that it is only the very worst cases which are not favourably affected. The usual dose given was one of 2,000,000 bacilli to an adult and proportionately less to children. The interval between the injections was reduced in the later observations, and that now advised is about four or five days with an outside limit of six. The dose should also be influenced by the nature of the case. If this is severe, and especially if it is of cerebral type, a dose of 1,000,000 bacilli for an adult and proportionately less for a child is advised. 3. On Myotonia, by T. Wardrop Griffith. Three cases of Thomsen's disease occurring in one family are described, and in two of these the symptoms were of special interest, since in one they were transient and in the other they diminished greatly in severity and ultimately disappeared. Under the name of myotonia atrophica et hypertrophica Dr. Wardrop Griffith describes a case in which there were symptoms of myotonia in a pronounced form accompanied by marked atrophy of some groups of muscles and an enlargement of those of the calves. In the light of his experience Dr. Griffith thinks that the view usually held that the condition never passes off is unduly pessimistic. The paper is illustrated by several plates. 4. The Distribution and Excretion of Radium and its Emanation after Internal Administration, by E. Bellingham Smith. It was found that after giving radium by the mouth or by injection a widespread degree of radio-activity is evident throughout the body, and that the elimination of radium takes place principally and rapidly by the bowel, and in a minor and slower degree by the kidneys. In mice there was no evidence that the liver or skin played any part in excretion. The emanation can be obtained in solution and can be introduced into the body by inhalation, feeding, or injection. It is eliminated chiefly by the lungs and to a very small extent by the kidneys. 5. Two Cases of Paroxysmal Bradycardia (Total), by

E. E. Laslett. In both cases the slow heart beat was paroxysmal and was due to a true or total bradycardia in which both auricles and ventricles participated. The condition was therefore in both distinct from heart-block. 6. Cardio-respiratory Murmurs, by Carey Coombs. The paper is based upon the notes of 180 cases. Two groups are differentiated: in the first the murmur is often associated with pulmonary collapse and is usually heard chiefly or solely at the base of the heart. In the second group it is best heard just outside the apex beat and is associated with pulmonary tuberculosis and nervous excitement. Dr. Coombs agrees with the view that in the second group, at any rate, the murmur is a peculiar type of friction sound. 7. Primary Occlusion of the Ostia of the Hepatic Veins, by Theodore Thompson and Hubert M. Turnbull. Three cases are described with full details of their microscopical characters, and a review of other published cases is given. 8. Critical Review: The Digitalis Preparations employed in Medicine, by W. E. Dixon. The various active principles are individually considered, and Professor Dixon concludes that pharmacological and clinical investigations have not made a clear case for the substitution of "active principles" for galenical preparations of digitalis in the treatment of patients. They are for the most part just as irritant as the infusion or tincture, and are neither more trustworthy and constant in action than a properly standardised tincture, nor are they absorbed more rapidly. The one advantage certain of them possess is that they may be given intravenously without ill-effects.

The Journal of Vaccine Therapy.—The first issue of a new journal, entitled the *Journal of Vaccine Therapy* and dated Jan. 1st, lies before us. It is edited by Dr. R. W. Allen and is published by Mr. H. K. Lewis at the price of 1*s.* per issue, or 10*s.* 6*d.* annually post free. We are informed that it is "founded neither in order to afford a medium for the undue pressing of the claims of Vaccine Therapy to a place in modern therapeutics nor to advertise the merits of any particular brand or brands of vaccines." The present number contains a paper by Dr. R. J. M. Buchanan on the Pathogenesis and Treatment of Rheumatic Fever and Chorea, in which the claim of "rheumatism" is upheld to be an acute specific disease and an infection. After a discussion on the treatment generally used, the author relates his experience, with illustrative cases, of a vaccine made from micrococcus rheumaticus, which he concludes has a definite effect on acute rheumatism when given early in the attack. In two cases it has shown a definite effect on the endocarditis. He does not depreciate the usefulness of the salicylates and other remedies, but considers that cases of rheumatic fever and chorea are assisted beneficially by the vaccine treatment. Dr. F. J. Sadler describes the vaccine treatment of typhoid fever, and Dr. R. W. Allen discusses Acne, its Causation and Treatment. The editor calls special attention to the fact that in reporting cases it is highly important to mention the immunising potency of the vaccines used (which differs materially in different products) as well as the dose given.

The Journal of the London School of Tropical Medicine.—The progress made by the London School of Tropical Medicine, since its establishment on a small scale in 1899, in the opinion of the school committee justifies the publication of a journal devoted to tropical medicine and conducted by the staff, together with the past and present students of the school. At first the journal is to be issued about the middle of each session—that is, three numbers in each year, the numbers to consist of about 100 pages each. The various articles will be arranged under the headings of Clinical Medicine, Pathology, Bacteriology and Hygiene, General Medical Zoology, Protozoology, and Helminthology, the teachers of these several departments at the school having charge of them. The editor-in-chief is Sir Patrick Manson, with Dr. C. W. Daniels as general editor, and Colonel A. Alcock, C.I.E., F.R.S., Professor R. Tanner Hewlett, Dr. R. T. Leiper, Mr. H. B. Newham, and Dr. C. M. Wenyon as sectional editors. It is published by Messrs. Taylor and Francis, Red Lion-court, Fleet-street, E.C., price 3*s.* each number or 7*s.* 6*d.* per annum. In the first issue, dated December, 1911, Colonel Alcock reviews some recent publications relating to medical entomology. Dr. A. Hutton writes on the Morphology of Oxyuris Ambiguus Rud: Type of the Genus Passalurus. Dr. Leiper contributes Notes of Recent and Some New Records of Helminthes in Man, of which there are few records; also a check list of Helminthes Parasitic in Equines, an account of a new Echinostome Parasite in Man, and a method for dealing with Town Wells Infested with Guinea-worm; Dr. F. P. Minett discusses the question of Flies as Leprosy Carriers; Mr. Newham has some Notes on the Examination of Rats for Plague and a consideration of the Leucocytic Variation in Trypanosomiasis; Dr. H. Bayon, Craggs Investigator, London School of Tropical Medicine, writes of Acid-fast and Acid-resisting Germs cultivated from Cases of Human Leprosy and their Determination, the results of his independent research, confirming almost in detail those of Captain T. S. B. Williams, I.M.S., whose work as well as that of Major E. R. Rost, I.M.S., has been already mentioned in our columns[1]; Dr. K. S. Wise deals with the Treatment of Leprosy in British Guiana; Dr. C. W. Daniels reports a series of cases of Trypanosomiasis in England, mainly at the London School of Tropical Medicine. There are in addition under each section abstracts of the more important communications relating to tropical medicine in the various journals.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Jan. 11th, Mr. RICKMAN J GODLEE, the President, being in the chair.

The SECRETARY reported the death, on Dec. 22nd last, of Professor O. M. Lannelongue, of Paris, an Honorary Fellow of the College. The President was requested to write a letter of condolence to the family.

Mr. R. H. Burne's resignation of the office of Assistant Conservator was accepted, and the best thanks of the Council were given to him for his valuable services to the College during the last 20 years in the offices of Anatomical Assistant in the Museum and Assistant Conservator. Mr. Burne was then appointed Physiological Curator.

The name of a Member of the College was ordered to be removed from the roll of Members; his name had previously been removed from the Medical Register.

The Council appointed Sir W. Watson Cheyne a member of the Court of Governors of the University of Birmingham in the vacancy occasioned by the retirement of Sir Henry T. Butlin.

Mr. Rickman J. Godlee, the President, was appointed Hunterian orator for February, 1913.

A letter was read from the Royal Commission on University Education in London, stating that the Commission would be obliged if the College would submit for its information a statement upon dental education in London and nominate a witness or witnesses to represent the College before the Commission. A committee was appointed.

A committee was appointed to watch the interests of the Fellows and Members under the Insurance Act, with power to confer with other committees formed with similar objects. The committee was instructed to report to the next meeting of the Council.

The PRESIDENT stated that the vacancy on the Court of

[1] See THE LANCET, June 3rd, 1911, p. 1538, and July 8th, 1911, p. 109.

Examiners occasioned by the expiration of the period of office of Mr. J. Ernest Lane would be filled at the ordinary meeting of the Council on Feb. 1st.

The PRESIDENT announced that the Lord Mayor (Sir Thomas B. Crosby, F.R.C.S.) would be the guest of the College at dinner on May 3rd.

BRITISH MEDICAL BENEVOLENT FUND.

AT the December meeting 22 cases were considered, and grants amounting to £161 were made to 18 of the applicants. As the current account was already overdrawn to the extent of £215, the deficit was consequently increased to £376, and the committee earnestly appeals for support to enable it both to pay off this overdraft and to deal with the very distressing and numerous applications which are always received early in the year. Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W. Appended is an abstract of the cases relieved:—

Wife, aged 25, of M.R.C.S., L.S.A. Husband had to be removed to an asylum a few weeks ago, and applicant, who is in very bad health, is practically destitute. One child aged 14 months. Voted £10.

Daughter, aged 27, of late L.R.C.P. Edin. Has been employed as a telephone clerk for the last ten years, but is in feeble health and has therefore decided to endeavour to support herself by letting lodgings. Voted £5.

Widow, aged 65, of L.R.C.P. Edin. Supplements an annuity of £20 by addressing envelopes, &c., but finds increasing difficulty in getting employment. Relieved 14 times, £141. Voted £5.

Widow, aged 53, of L.R.C.P. Edin. Has been deprived of a home by the recent death of a relation, and is dependent on a few shillings a week allowed by her mother-in-law. Relieved four times, £20. Voted £10.

Wife, aged 48, of M.R.C.S. Is separated from her husband through no fault of her own, and endeavours to support herself and six children, aged 17 to 9, by letting lodgings. Relieved twice, £24. Voted £5.

Daughters, aged 57 and 53, of late M.R.C.S. Health indifferent, and attempt to maintain themselves by taking lodgers or boarders, but have had a very bad season. Relieved seven times, £84. Voted £12.

Widow, aged 66, of L.R.C.P. Edin. Only income £20 a year from a small house, of which the lease has nearly expired. Relieved 12 times, £138. Voted £12.

Widow, aged 65, of M.R.C.S., L.S.A. Quite unprovided for at husband's death about 12 months ago, but hopes to support herself by taking a resident patient or boarders. Relieved once, £6. Voted £6.

Widow, aged 52, of L.S.A. No income and entirely dependent on her earnings from needlework, in which she is assisted by the younger of two daughters. Elder daughter, aged 18, earns a few shillings a week by teaching. Relieved five times, £46. Voted £12.

Widow, aged 63, of L.S.A. Only income £12 a year; children unable to give more than slight help. Relieved twice, £24. Voted £12.

Widow, aged 50, of M.R.C.S. No income, and is endeavouring to establish a boarding house. Relieved twice, £20. Voted £10.

Daughter, aged 62, of late M.D. Edin. Used to be a companion, but gave up her post a few years ago to nurse her two elder sisters, who are both chronic invalids. Only income £10 a year allowed by a friend. Relieved six times, £72. Voted £12.

Widow, aged 47, of L.K.Q.C.P.I. Quite unprovided for at husband's death and dependent on letting lodgings and needlework. Relieved once, £5. Voted £5.

Widow, aged 74, of M.R.C.S. Has a small income, but asks for a little help to meet quite unavoidable expenses. Relieved once, £12. Voted £5.

Widow, aged 61, of M.R.C.S. Quite unprovided for at husband's death three years ago, and finds great difficulty in obtaining a suitable post even in exchange for a home. Relieved twice, £26. Voted £12.

Widow, aged 66, of M.R.C.S. Is quite destitute except for small uncertain earnings from needlework. Relieved twice, £24. Voted £12.

Widow, aged 83, of M.R.C.S. Only means of support an annuity of £10 and an old age pension of 5s. a week. Relieved once, £6. Voted £6.

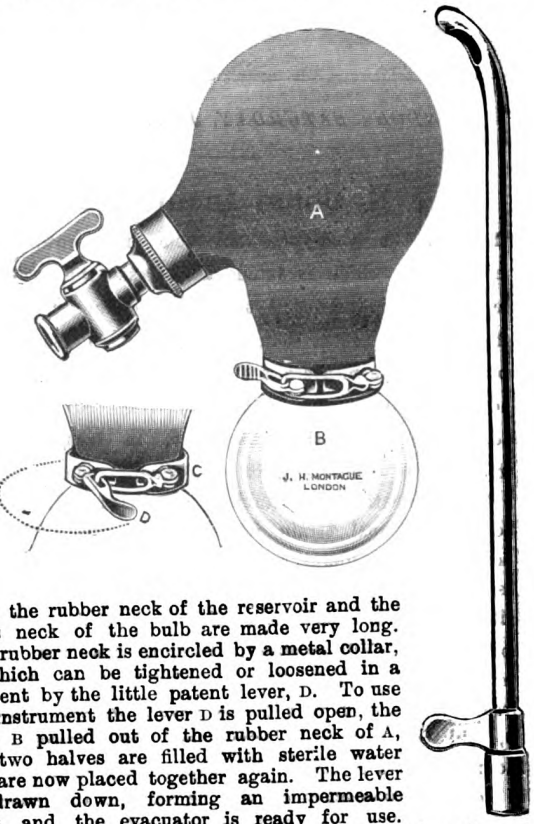
L.S.A., aged 67. Practises in a thickly populated neighbourhood, but finds great difficulty in getting paid, and is in consequence in arrears with his rent. Health very indifferent. Relieved twice, £36. Voted £10.

New Inventions.

A NEW EVACUATOR FOR LITHOLAPAXY.

MOST evacuating bottles used in the operation of lithola-paxy are made with two metal collars, one fixed to the neck of the rubber reservoir, the other fixed by cement to the glass neck of the bottle. The instrument is "assembled" by fixing the glass bulb to the rubber bottle by means of a bayonet joint on the two metal collars. This is a perfectly adequate means of "fastening" the two halves of the evacuator together, but it labours under the grave disadvantage of making it impossible to sterilise the instrument by boiling. After boiling once or twice the cement fixing the metal collar to the glass becomes loose, and the instrument first begins to leak and very shortly the glass and metal come apart. Mr. J. H. Montague, of 69, New Bond-street, London W., has, at my suggestion, made an evacuator which can be boiled again and again without this disadvantage.

The accompanying illustration shows the method adopted. A is the rubber reservoir, B is the glass bulb.



Both the rubber neck of the reservoir and the glass neck of the bulb are made very long. The rubber neck is encircled by a metal collar, C, which can be tightened or loosened in a moment by the little patent lever, D. To use the instrument the lever D is pulled open, the bulb B pulled out of the rubber neck of A, the two halves are filled with sterile water and are now placed together again. The lever is drawn down, forming an impermeable joint, and the evacuator is ready for use. After a certain length of time the rubber where it is embraced by the metal collar tends to perish, but as the rubber neck is very long it is only necessary to cut off the perished portion.

I have now had this instrument in use for a considerable time, and find that it gives me every satisfaction.

London, W. JOHN PARDOE, F.R.C.S. Eng.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the above society was held on Jan. 10th, at 11, Chandos-street, Cavendish-square, W., Dr. Walter Rigden, senior vice-president present, in the chair. Fourteen directors were present, amongst them being Sir Thomas Crosby, Lord Mayor of London, one of the vice-presidents who consented to be nominated as President of the society, to fill the vacancy caused by the death of Dr. G. F. Blandford. Since the last court one of the vice-presidents of the society, Sir Samuel Wilks, has died. Three gentlemen were elected members of the society. The sum of £1288 10s. was voted for the payment of the half-yearly grants to the annuitants of the charity. The grants to the orphans have been increased from £15 per annum to £25. The invested funds of the society now amount to £101,600. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross. The annual subscription is 2 guineas, but life membership may be obtained by the payment of one sum, the amount of which depends on the age of the candidate. Relief is only granted to the widows and orphans of deceased members, and letters are constantly being received from widows of medical men asking for relief, but this has to be refused as their husbands had not been members of the society. Application forms for membership and full particulars may be obtained by application to the secretary at the offices of the society, 11, Chandos street, Cavendish-square, London, W.

THE LANCET.

LONDON: SATURDAY, JANUARY 20, 1912.

The National Insurance Act.

DURING the week the movement has grown among medical men which is intended to resist the working of the National Insurance Act until far stronger and more categorical safeguards than are conveyed to them by the wording of the measure are forthcoming. The protesters find that under the Act they may be overworked and badly paid; that they are, in fact, offered a remuneration which is quite inadequate, when the cost of their education, the anxious nature of their services, and the physical strain involved in those services are taken into consideration. Mr. WILFRID TRAVERS, the business manager of the Reform Committee of the British Medical Association, informs us that the accommodation in Villiers-street, Strand, has not proved commodious enough for the volume of business which has already arisen, and that offices have now been opened at 29, Old Queen-street, Westminster. The Committee, we understand, are receiving wide support to their demand for an Act of Parliament amending the National Insurance Act, in accordance with the declared object of the organisation, as settled at the recent Hammersmith meeting and reported in our columns; and it is to this end that appeal is made to members of the medical profession to join the movement. We trust that the Committee will appreciate the difference between those who join them out of a mere facile adherence to their programme, with the idea that some good must come out of any organised resistance, and those who give definite promises of work to secure the carrying out of that programme.

We cannot ourselves feel sanguine that sufficient influence can be brought to bear upon the Government to obtain an amending Act which shall categorically secure for the medical profession the position laid down by the six cardinal points. The attitude of the Reform Committee in demanding such amendment, however, is entirely logical. A number of members of the medical profession declared, almost as soon as the provisions of the measure were made public, that they would not work under a scheme which did not meet what they maintained to be their just claims to consideration, and these they put in the form of an irreducible minimum. The measure became the law of the land without securing for the medical profession that minimum, although the Council of the British Medical Association were willing to believe that sufficient had been granted, and that the position of medical men under the Act was properly safeguarded. The Reform Committee, representing a large body of practitioners who cannot be persuaded to the same belief, therefore ask for immediate legislation amended in directions which they have declared over and over again to be necessary. But although this demand is, as has been said, entirely logical, the Committee cannot possibly hide from themselves that to enforce it will be very difficult. For our part, while the courage and sincerity of the Reform Committee are undoubted, we cannot help wishing that they had not taken their stand solely upon the six cardinal points, for we believe that their object could have been as well attained by a resolute intention to see that the regulations under which the work will have to be done are just and adequate—are, in fact, such as take our professional position into better consideration than the various sections of the Act appear to. There can be no attempt made to conceal the fact that the massive support of the six cardinal points has been obtained on a coöperative principle, many members of the medical profession having little hope that the most debated one of these points will be granted, and having not much enthusiasm for another point; but, none the less, all, through loyalty to their fellows in the mass, supported the six-fold claim. In these circumstances it certainly seems to us that it is on the regulations that we should keep our attention fixed, for here it is still within the power of a strong and united profession to effect much, and here it is that we can turn from criticism to construction. The resolution not to work under the Act unless these regulations are satisfactory will, in the first case, help the framing of workable regulations, and may, in the second case, lead to the introduction into them of a flexibility which in the present position seems to us necessary. For the Act provides *sickness* benefits and *medical* benefits; and while the former can be paid for in coin of the realm from the same mint, the latter has to be supplied by a service that must be rendered in different places under different conditions. Medical men are one in their aims and one in their training to this extent, that all the medical education of this country is a highly standardised and expensive affair; but while, so far, we are homogeneous, our material interests in the practice of our profession lie in many opposite and sometimes conflicting directions. With a repetition that may be becoming tedious, we must point out that the great fault of the National Insurance Act is the way in which the medical profession, honoured with little attempt at consultation and imperfectly understood in so many ways, has been arbitrarily treated as a section of the community whose methods of gaining a livelihood, being all of one pattern, can at a moment's notice be turned upside down in order to conform to another pattern, without injustice to anyone. We are quite willing to grant that in such a general dislocation of affairs some medical men may benefit in their pockets, and it is possible that some may gain a certain security in their methods of livelihood; but against this must be put the certain fact that many others will be dire sufferers. No regulations of the Commissioners, so far as we can see, can possibly set aright all the wrong that will be done, but undoubtedly the way in which they are framed will prove of enormous importance.

Failing, then, the promotion of a new measure, which

indeed, we find to be a too sanguine expectation, the medical profession will have to bring all its energies to bear upon the securing of proper regulations. And we are perfectly confident that the more a stand is taken upon a professional basis and the less the methods of the trades union are employed, the better will be the result. Already there is much to warrant the belief that this Act, though it is not now treated by its parents as a provisional measure, is none the less regarded by them as open to criticism, indeed as having imperfections to be removed. The Chancellor of the Exchequer has declined to give any pledge with regard to such amendment, but Sir JOHN SIMON, the Solicitor-General, introducing Mr. ORME CLARKE'S exposition of the Act, which we review elsewhere, speaks of amendment as quite certain. The profession would welcome now the intervention of the great medical corporations as guides to a constructive policy.

Imagination in Medical Research.

THE great surgical philosopher of the first two-thirds of the nineteenth century, in the course of a presidential address to the Royal Society, described imagination as the faculty which, "properly controlled by experience and reflection, becomes the noblest attribute of man; the source of poetic genius, the instrument of discovery in science, without which NEWTON would never have invented fluxions, nor DAVY have decomposed the earths and alkalies, nor would COLUMBUS have found another continent." He could not have uttered such words without making a mental application of them alike to the science and art to which his own life was mainly devoted, and also to the kindred pursuits of the physician; and, indeed, it is manifest that imagination, as the parent of hypotheses explanatory of observed phenomena, and themselves capable of being brought to the test of experiment, is the ultimate source of all useful knowledge of the facts of life. Many of us have heard of the two students who reported upon the same patient in competition for a clinical prize. The patient presented, among other symptoms, a remarkable discoloration of a certain area of skin, and the first student described this discoloration with the most careful minuteness. He measured it in different directions and drew a rough sketch of its general outline. The second observed the phenomenon with equal care, but he exercised his imagination and formed a hypothesis which he proceeded to bring to the test of experiment. He asked a nurse for a wet towel, with which he wiped the discoloration away. It is evident that the faculty which he thus brought to bear upon the problem before him would be likely to stand him in good stead in relation to many others of a more complicated character; and that his exercise of the art of diagnosis would be practically immune from the errors incidental to the habit of taking all appearances at their face value. Imagination at once points to the possibility of more than one explanation of any given occurrence, or alleged occurrence, and compels inquiry as to the existence of probable causes beyond the particular one which may at first sight appear to have been in operation. But, as BRODIE said, it must be properly controlled by experience and reflection, lest it should become a source of error by inducing the acceptance of hasty and ill-considered suggestions. When the new Insurance Act comes into practical application, whatever the terms accepted by the medical men may be, those who serve under it will find ample scope for imagination in their endeavours to keep abreast of what may otherwise become a very science of malingering.

In dealing with medical and surgical problems generally, or as they affect communities rather than individuals, imagination must always be the initial factor in the conduct of research, and the chief signpost on the road towards discovery. To take the most important and most conspicuous of modern examples, it was imagination that first pointed to the mosquito as an agent in the conveyance of disease to man. Dr. (now Sir) PATRICK MANSON was in practice at Amoy, and his attention was called to the occasional presence in the blood of the natives of the minute larval filaria which had been discovered by BANCROFT and called after his name. This was seen under the microscope as a motile thread about 0·3 mm. in length by 0·008 mm. in diameter, completely inclosed within a capsule, and present in the blood in millions, but occasioning no apparent symptoms. Dr. MANSON employed Chinese hospital assistants to obtain blood-smears from as many natives as possible in order to ascertain the degree of frequency of the creature among the population. One of his blood collectors was greatly more successful in obtaining the filariæ than others, and inquiry showed that his specimens of blood were taken chiefly in the evening. Further inquiry showed that the filariæ swarmed in the evening in the blood of the superficial vessels of those of their bearers who worked by day and rested at night, and that they swarmed in the morning in the superficial blood of those who reversed this process, such as watchmen and other followers of night industries. A post-mortem examination of a day worker who died suddenly in the morning showed the lungs, the heart and great vessels to contain millions of filariæ, while the superficial vessels were free from them; so that their usually nocturnal migration to the surface was presumably due to changes produced in the blood by fatigue. Why should this migration occur? Dr. MANSON brought his imagination to bear upon the problem, and it suggested to him that the filariæ were parasites requiring the intervention of a second host in order to enable them to reach their next phase of existence, and that their nocturnal migration pointed to this host as being a nocturnal creature of blood-sucking habits. Among such the mosquito presented itself for inquiry, and a Chinaman infested by filariæ was hired to spend a night with a selected company of the insects. In the morning they were captured, gorged with his blood, and by dissections conducted on successive days the filariæ were seen to pass through the next stages of their existence in the muscles of the insect, and to return to the extremity of the sheath of its proboscis, ready to be deposited upon the surface of the next human victim in the immediate vicinity of the puncture, and to make their way through the skin to his lymphatics prepared to undergo complete development into nematoid worms

and to propagate their kind. So far all that was done was to elucidate the growth of the parasites which produce lymphatic varicosities and elephantiasis; but shortly afterwards LAVERAN discovered the parasite of malaria. Dr. MANSON'S imagination at once took fire, and he pointed out that, in all probability, a mosquito was the instrument of its conveyance to mankind. Unable to pursue the investigation himself, he explained his views to Major (now Sir) RONALD ROSS, to whom he also imparted the technique of mosquito dissection which he had himself employed, and who, after much patient and laborious research, was able three years later to confirm what Dr. MANSON had suggested, and thus to establish on a sure basis a discovery which will ultimately lead to the extirpation of a large group of serious or fatal diseases, and may rank with the discovery of anæsthetics or of aseptic surgery.

And, even when we approach the subject of prognosis, the chastened play of the imagination among possibilities should rather be encouraged than restrained. We need its help in order to picture to ourselves the infinite and never-ending struggle between the invading sources of disease and the several "antibodies" which the blood provides for their destruction and the provision of which may be augmented by resources of which medicine is only now beginning to avail herself. We manifestly need its help more when we attempt, by such resources as the microscope and the laboratory will afford, to forecast the issue of the struggle in the case of an individual, or still more, in the case of a disease which has only comparatively lately been brought within the sphere of scientific observation, such as the epidemic poliomyelitis which has recently affected children in many parts of Europe and of America. We have not only to identify the assailants where this is possible, but also to use the ordered play of the imagination in our efforts to establish firmly the lines of defence, and to provide the garrison by which they must be occupied. We have to guard both ourselves and the patients who confide in us against what has been described by an illustrious man as "the bane of half-knowledge," and we can only do this by fearlessly carrying exploration to its farthest possible limits, and by taking account of every circumstance which may affect the accuracy of our forecasts, whether they relate to individuals or to communities. For work of this description the imagination is the motive force of the intellect; and, without the impulse which it affords, our progress would at the best be slow and uncertain, even if it were not altogether arrested. The one thing necessary for its safe employment is that the philosopher should not be too much enamoured of the pictures which it supplies, and should be equally prepared to accept or to reject them as the results of experimentation may require. In other words, he should "love truth better than his system," while recognising that, without a system, his prospects of attaining a knowledge of truth would be very sensibly diminished. JENNER once wrote to JOHN HUNTER that he "thought" so-and-so, and HUNTER replied, "Don't think, try." It would, perhaps, be presumptuous to describe the advice as "bad," but at the best it was, at least, incomplete. Without "thought" there is no room for "trial," and no one knew this better than a finished experimenter like HUNTER. What he meant was clearly, "Don't rest at thinking. Pass your thoughts through the filter of experiment and accept only what the filter retains." In other words, exercise your imagination to the full, but be careful afterwards to correct and to control its operations.

State and Voluntary Sanitary Control of Workshops.

UNWHOLESOME dwellings are the greatest drawbacks to the industrial communities of all nations, but second only to them in sinister influence come unwholesome workshops. There is a formidable array of special trade diseases which can only be checked by the anxious supervision of the premises wherein the trade is pursued, and to this list there must be added ordinary diseases which are accelerated or rendered more frequent or more fatal by the insanitary condition of the factory. In spite of the many statistics published we do not know the full extent of the mischief done by keeping men and women at work in unsuitable premises. Some of the States in America are making notable efforts to thoroughly elucidate the subject, and what is being done is worthy of note, even though we cannot all agree of its practicability. The State of Wisconsin has enacted a law requiring medical practitioners to report to the Board of Health all cases of poisoning due to mercury, lead, arsenic, and phosphorus contracted through the patient's occupation. Cases of illness arising from work done in compressed air, caisson work, and so on, must be notified. Blank forms are sent to all the practitioners so that the reports made may be uniform. The name, address, the place of employment, and nature of the disease have to be inscribed on these forms. The State of Michigan, facing Wisconsin but on the eastern side of the great lake, has a similar law. All medical practitioners in this State are compelled to notify to the State Board of Health every case of disease caused by the work on which the patient is engaged. The name and address must be given, the length of time the patient has been employed, and the duration of the disease. All this information will in the final stage be remitted to the Commissioner of Labour and presumably will be used as a basis for further legislation. Such notification of certain industrial diseases resembles the factory enactments in this country of 1895 and 1901, while the suggestion of a wider notification to include all industrial diseases hardly seems to us workable from the practitioner's point of view—at any rate, as yet. Under our present legislation certain maladies are scheduled as *primâ facie* due to certain employments, but it is always a controversial question, for judicial decision if need be, how far the disease is due to employment and how far to outside conditions. To make the practitioner the referee on such points is to place upon him a very heavy responsibility.

While Michigan and Wisconsin are thus taking steps to extend the scope of legal interference in defence of the health of the workman, a move in the State of New York towards using voluntary organised efforts

to the same end should be noted. A considerable number of employers and employees have agreed to form "a Joint Board of Sanitary Control of the Cloak, Suit, and Skirt industry of New York City." The idea is to define a standard of sanitary conditions to be established and maintained in all the workshops. Both the employers and the workpeople have pledged themselves not to work in cellars or workshops in the rear of houses or attics unless, after examination of the methods of lighting and ventilation, special permission is given. Then the rules accepted give very full details in regard to outside fire ladders and the various means of fire escape, the provision of automatic sprinklers and chemical extinguishers. Special caretakers must be appointed to see that the fire buckets are always full of water, that no doors are locked during work hours, and that no one smokes in the workshops. The ways of exit must be very clearly indicated and the stairs safe to tread, of easy access, and well illuminated. Every workshop must have a large window-space, so that no part shall need artificial light during the daytime. When, in winter, artificial light must be used, incandescent mantles are recommended. The lights must be shaded and placed above and not too near the workers. At least 400 cubic feet of space shall be provided for each worker, and large pieces of furniture or materials must not be included in this space. Before and after the work hours and during the lunch hour all the doors and windows must be opened to give the premises a thorough airing. All floors are to be scrubbed once a week. Separate lavatories for each sex have to be provided, kept clean, well lighted and ventilated. A lunch-room, a dressing-room, and suitable contrivances to hang up the clothes worn in the streets have likewise to be placed at the disposal of the workpeople. It is only when all these rules have been satisfactorily applied that a sanitary certificate is granted by the Joint Board of Sanitary Control.

The success of such a movement must largely depend upon the public. The public-spirited employers who have consented to hamper themselves with all these restrictions, which must add considerably to their working expenses, expect some recognition at the hands of the public. They hope that the purchaser will inquire whether the clothes he proposes to wear have been made up in a workshop that has received the sanitary certificate. If this is done the movement will be of great use to the purchasers and the producers, but if the former will not give themselves the trouble to look after their own interests they cannot expect that tradesmen will long continue to make sacrifices on their behalf. If the "tentative" move on the part of a certain section of a certain industry in New York should be widely taken up great good will follow, but our experience in this country is not very hopeful. There is with us very little pressure of the practical and moral kind that is hoped for, exercised by the purchasers over the manufacturers—even the demand for leadless glazes has been fitful, we believe. Our Home Office is trying earnestly, and for that matter successfully, to get employers and workmen to agree upon structural and other precautions to be observed under the various Acts, and a long and growing list of regulations gives yearly more protection to those engaged in processes which are clearly dangerous. That there should be behind the State in such matters the steady support, not only of public opinion, but public action, is devoutly to be desired.

Annotations.

"Ne quid nimis."

THE EPIDEMIOLOGY OF ACUTE POLIOMYELITIS.

THE occurrence of large epidemics of poliomyelitis in Northern Europe and in America and of small outbreaks in various parts of this country, as well as the discovery of important facts in regard to the causation and spread of the disease, have enormously increased the interest taken in this subject. We have on several recent occasions commented upon various publications on the disease and upon the administrative measures suggested to combat its incidence and spread. In a disease of epidemic nature occurring in children it is natural to inquire what part, if any, is played by schools in its spread. This question is discussed in an interesting and critical manner in a paper read before the Medical Officers of Schools Association on Nov. 8th, 1911, by Dr. Frederick E. Batten,[1] whose researches upon the nature of this disease are well known. Dr. Batten first reviewed the clinical varieties of the disease and the history of the discovery of the virus. He stated that the virus will not grow on any of the ordinary media, and that it has not yet been stained or seen under the highest power of the microscope. It can be shown to be present in the mucous membrane of the nose and in the salivary glands of an infected monkey. It has only been found possible to transmit the disease to monkeys of all the animals which have been inoculated with it; and whether introduced by the brain, the peritoneum, or by intravascular, intraneural, or subcutaneous injection, the disease became established in the spinal cord. The exact period of incubation is as yet uncertain, but in 65 out of 81 monkeys it was under 12 days. The clinical evidence seems to suggest that it is less than six days. The infectivity of the disease appears to be not very great, the proportion of persons exposed to infection who develop the disease being 6 per cent., whereas with scarlet fever and diphtheria it is 22 and 17 per cent. respectively. Dr. Batten, in reviewing the evidence in favour of the spread of infection by schools, described the observations of Wickman in the Swedish epidemic. This observer found that the disease tends to travel along the railways and great thoroughfares, and he cited four instances where there was evidence that the disease was spread by schools. The evidence with Wickman's tables is carefully presented by Dr. Batten. The most important epidemic investigated from this point of view was that at Trästena, a small community of 500 inhabitants, consisting of 132 families living in 102 houses. In rapid succession 49 people were taken ill, the majority being children, and of the 49 cases 26 were paralysed. The relation of these cases to attendance at school is shown in a simple manner by a diagram. Dr. Batten concluded that there is no doubt that the virus was transmitted from person to person and that it was often carried by an intermediate person who was not suffering from the disease. It is also clear that this epidemic was not carried by water or by milk. Other outbreaks in Sweden, Berkshire County, N.Y., and Westmorland are also considered in similar fashion. Dr. Batten next reviewed the evidence against school infection, which is, in brief, that 75 per cent. of the

[1] Medical Officers of Schools Association. Poliomyelitis in Relation to the Spread of Infection by Schools. By Frederick E. Batten, M.A., M.D. Camb., F.R.C.P. Lond. London: J. and A. Churchill. 1911. Pp. 16. Price 1s. net.

cases occur before the age of four years—i.e., before the school age, that it is very rare for the disease to occur in an epidemic form in institutions, and, further, that in hospitals where cases of poliomyelitis are admitted the disease has never been known to spread. Dr. Batten summed up by expressing the opinion that the evidence in favour of the spread of infection by schools is not conclusive, but that it is a possibility which should be borne in mind. He advised that all contacts should be submitted to a period of 14 days' quarantine before returning to school. In infected cases he suggested that they should not return to school until at least a month after the onset of the illness, and only then if convalescence is complete and there is no discharge from the nose. In severe cases the resultant paralysis by itself prevents a return to school for months. We have also received a copy of a report presented to the Health Committee of the City of Carlisle by Mr. Joseph Beard, medical officer of health, upon an epidemic of the disease which occurred in the late summer and early autumn of 1910. There were 38 cases, with seven deaths. At an early period, on the recommendation of Mr. Beard, the Health Committee adopted a system of voluntary notification, which received the sympathy and coöperation of the local practitioners, with the result that useful information was obtained. Mr. Beard strongly urges the importance of universal notification of this disease.

HYGIENE AND THE TUBE BOOKING-CLERK.

IN the scales of legal justice the question of intent or wilfulness is commonly allowed its full weight either for or against the offender, so that, for example, a man charged with inflicting bodily hurt can, if he proves the inadvertence of his act, rely on the leniency of the court. In breaches against the public health, on the other hand, this plea is less satisfying, and rightly so, otherwise the careless householder, for instance, whose insanitary manners have spread an epidemic of infectious disease among his neighbours, might escape the pecuniary responsibility for his sins. Often, moreover, the effects of a dangerously unhygienic act, itself entirely inadvertent, can, if traceable to their origin at all, be linked up to it only with much difficulty, at any rate by a chain of legal proof. Thus a parent may innocently allow his child, while still desquamating from scarlet fever, to attend a gathering of other children many of whom are as susceptible to the disease as straw to a match. As with individuals, so with commercial enterprises. Every year in the London tube railways millions of the public avail themselves of the comforts and conveniences of subterranean travel. Each of these passengers, each time he goes by tube, receives a ticket handed to him by a booking-clerk, whose movements, hidden behind his pigeon-hole, are in most instances not noticed, perhaps not even seen. To the observant, however, the habits of the booking-clerk are of no little hygienic interest. At a first glance it would seem that on the receipt of the appropriate fare he immediately tenders a ticket to the purchaser who carries it in his hand to the liftman to be punched, and then places it safely in his pocket. Looked at more closely, however, the incident gains in significance. It may now be noticed that the clerk, when addressed by the passenger, first inserts one finger (sometimes two) into his mouth, for all the world as though he had burnt his hand, then, withdrawing it rapidly, tenders the requisite ticket. This ticket, now wet with the clerk's saliva, is picked up by the passenger, to whose fingers a portion of the moisture may adhere, is grasped by the ticketman at the lift, whose fingers may also receive a portion, and is finally conveyed to the passenger's pocket, under the warmth of which the remaining portion evaporates, leaving the residual particles to rub against the dark recesses of the lining. This sequence of events, of course, is subject to alteration. The booking-clerk is only human and sometimes he forgets to lick his fingers. Sometimes his occupation is taken from him by an automatic ticket machine or by the system of "strip-tickets"; but often—very often—the passenger, in return for his pence, may find that he is bearing away on his ticket a generous quantity of the booking-clerk's saliva. It may at once be granted that, in all probability, not many of these clerks are consumptive or are infected with any contagious disease. The practice is insanitary. If, as may be the case, it is the outcome of the contrivance by which the tickets are kept ready to hand in the booking-office, and by which an unmoistened finger is placed at a mechanical disadvantage, the difficulty might be met by a damping-pad beside each pigeon-hole. Certainly a progressive and enlightened railway company that not only provides its weary passengers with ozonised air, but exhorts them by public notice and under penalty not to spit, will hardly be backward in putting an end to this gratuitous distribution of their employees' saliva.

ACUTE PHLEGMONOUS GASTRITIS WITH ERYSIPELAS.

ACUTE phlegmonous gastritis is very rare and the number of cases which have been investigated bacteriologically is limited. The organism which has been most often found is the streptococcus, but Mr. J. E. Adams has reported in our columns a case due to the pneumococcus.[1] As erysipelas is due to a streptococcus, the suggestion has been made that phlegmonous gastritis is "erysipelas of the stomach." In the *American Journal of the Medical Sciences* for November last Dr. W. S. Baird has reported a case from the Pathological Laboratory of the Montreal General Hospital in which erysipelas, as well as general infection with the streptococcus, was present. A man, aged 30 years, was admitted on April 26th, 1910, complaining of dyspnœa, swelling of the legs, and vomiting. The pulse was 136, irregular, and of small volume. The heart was enlarged, and an apical systolic murmur transmitted to the axilla was present. There were œdema of the legs and thighs and tenderness over the epigastrium. The tongue was coated, and as soon as food was taken it was vomited. The liver was palpable, but the patient stated that he took only one or two glasses of beer or whisky daily. He was discharged improved on May 14th, but he relapsed and was readmitted on June 9th. In addition to the previous symptoms there was evidence of right pleural effusion, and the abdomen was prominent but not tender or dull in the flanks. The œdema disappeared, but he did not improve, and suffered from pain in the epigastrium and præcordium. Severe hiccough and vomiting developed. On June 16th erysipelas began on the nose and soon spread over the cheeks. The temperature was elevated and the præcordial pain and dyspnœa increased. Delirium followed, and the epigastrium became acutely tender. On June 19th he became much worse and complained of acute sudden pain in the epigastrium; the dyspnœa became much more severe, the pulse failed, and he died. At the necropsy the peritoneum was found covered with a viscid exudate and deeply congested. In the recesses and pelvis were over 300 c.c. of thick, yellowish fluid, smears from which showed Gram-positive cocci in chains. The stomach was greatly distended and dark bluish-red. The right pleura was deeply congested and contained 300 c.c. of turbid yellow fluid, smears from which showed Gram-positive cocci in chains. The heart weighed 500 grammes and was much dilated. Shining through the epicardium of the left ventricle were two round, elevated, light yellow œdematous areas, about 1 centimetre

[1] THE LANCET, Jan. 29th, 1910, p. 292.

in diameter, smears from which showed Gram-positive cocci. The stomach contained thin, yellowish turbid liquid. The mucosa was deep red and velvety in appearance, and was covered with a thin tenacious layer of yellowish mucoid material. The gastric wall for a distance of 15 to 18 centimetres from the œsophageal orifice varied in thickness from 4 to 8 millimetres. This was due to infiltration of the submucosa, which on section exuded drops of thin, yellowish pus. Smears from this showed leucocytes and chains of Gram-positive cocci. Other lesions found were central necrosis of the liver, septic spleen, cellulitis of the left crus of the diaphragm, fat necrosis about the cardia of the stomach, congestion and infarction of the lungs. Cultures from the heart's blood and the walls of the stomach yielded streptococcus pyogenes. Phlegmonous gastritis may be secondary to lesions of the stomach or an acute infection elsewhere in the body, or be part of a general septicæmia. It is often difficult or impossible to determine the primary lesion. In the present case it seemed that the erysipelas was primary and that the other lesions were part of a general septicæmia.

THE HEALTH OF PROFESSOR TRENDELENBURG.

WE publish in another column the oration delivered before the Hunterian Society last week by Mr. C. A. Ballance. In the course of his oration he describes the wonderful operation performed by Professor Trendelenburg in a case of pulmonary embolism, and has since received a letter from Professor Trendelenburg which will be of interest to our readers as telling the early history of the operation for pulmonary embolism. The following is an abstract of the letter, which is dated Jan. 11th, 1912: "I have hitherto had no success with the operation for pulmonary embolism, and must now leave it to others to bring about the first success, for I have been obliged to resign my office on account of ill-health. I have not hitherto published my experiences lest I should discourage others from undertaking what is certainly a rational operation. I am, however, very pleased to communicate to you my cases. The two already published you know about. To them should be added ten cases which have subsequently been operated on in my clinic mostly by my assistants, and of which I give you a list. In all death followed shortly after the operation, which in most was undertaken too late. The two cases already mentioned and that of Krüger in which death did not occur till some days after the operation from suppurative pleurisy, are, up to the present, the most successful. In every case we are convinced that the operation was fairly simple and in favourable circumstances, which, however, can but seldom occur, ought to succeed. It has been stated that the diagnosis of embolism is too difficult and uncertain. This is not the case when we have to do with surgical patients suffering from fractures, operation cases, and so forth, who were previously sound. In all our cases of this nature the emboli in the pulmonary artery were found. We only failed to find the embolus in one case which was sent to me from the medical side moribund, with the diagnosis of pulmonary embolus. I have not included this case in my list. In doubtful cases and in cases of embolus or thrombosis without severe symptoms, we have been accustomed to bring the patients into the operation theatre and to wait. In two such cases the symptoms of embolism subsided and recovery followed. In seven cases the course was so rapid that no question of an operation could arise. After these experiences I believe that in spite of the failure that has hitherto attended it the operation for pulmonary embolism has a future. The resolution to operate has not been in most cases taken sufficiently promptly, and perhaps also improvement in the technique is required." All British surgeons will learn with the deepest sympathy and regret of the illness of Professor Trendelenburg, whose name is so well known and honoured in every surgical clinic. The operation for pulmonary thrombosis is not the only advance in the surgery of the venous system which we owe to him. The brilliantly successful results which have followed ligation of the ovarian veins in puerperal septicæmia will ever be associated with his name. After 45 years of strenuous hospital work it is to be hoped that this noble life will long be preserved to contribute further to the science if not the art of surgery.

A MEDICAL MAN'S BEQUEST.

THE late Dr. Charles Alfred Lee, the senior medical practitioner of Hull, who died, unmarried, on Jan. 13th, has left by his will £155,000 for charitable purposes. The greater part of this munificent bequest is to be devoted to the building and endowment of almshouses for the city of Hull. Throughout his long life Dr. Lee was a generous supporter of local charities, and one of the wards in the Hull Royal Infirmary, as well as a home for sailors' orphans, bear his name. The scheme for the erection of almshouses, which is outlined in the *Eastern Morning News*, is on a very large and comprehensive scale; and one of the last acts of the donor's life was to sign the deed of conveyance of the 4¼ acres chosen by him to be the site of his foundation. The project interested him deeply, and his will gives clear directions for the equipment and maintenance of the institution and for the selection of its inmates. "Lee's Rest Houses," when completed, will stand as a lasting memorial to the charity and public spirit of a medical practitioner.

THE ETIOLOGY OF YELLOW FEVER.

A USEFUL purpose is sometimes served by "taking stock" of the state of our knowledge of a particular disease, and by passing in review the evidence upon which our opinions regarding it have been based. A recent instance of the value of this "stock-taking" is furnished by Dr. Harald Seidelin, the editor of the *Yellow Fever Bureau Bulletin*, who has contributed to the November number of that journal a very thoughtful and suggestive article in which he discusses the evidence upon which the modern etiology of yellow fever is based. He is well qualified for the task seeing that he has had both personal and practical acquaintance with the disease in one of its endemic areas, and has been for some years engaged in scientific research in regard to it. Though apparently a firm believer in the modern doctrine which ascribes the spread of the malady to the agency of a species of mosquito, Dr. Seidelin does not hesitate to criticise freely the evidence which has been adduced in its support, and to indicate the lines on which further investigation ought to proceed. The view that yellow fever infection is conveyed to man by the bites of the stegomyia fasciata is based mainly upon experiments carried out by Reed, Carroll, and Agramonte of the United States Commission more than ten years ago. It is now suggested that these experiments were not conducted altogether under ideal conditions, and that therefore they do not afford absolute and conclusive proofs; Dr. Seidelin contends that the transmission of yellow fever by means of the S. fasciata has not been proved beyond doubt on strict scientific principles in the way that the transmission of malaria by the anophelines has been demonstrated. It is, however, admitted that the arguments adduced in support of the theory are very strong, and that for practical purposes they may after all be accepted. Corroboration, moreover, is found in the fact that prophylactic anti-mosquito measures based

upon the theory have succeeded, when efficiently enforced, in causing the disappearance of the disease in places which were formerly much afflicted by it, as, for instance, at Habana and Rio de Janeiro, where previously other prophylactic methods had been found utterly futile. Other points associated with the modern etiology of yellow fever are also discussed by Dr. Seidelin, and he indicates that although the inferences already drawn regarding them may be perfectly correct, yet the evidence adduced in their support has been quite insufficient. Further confirmation is therefore very desirable before these points can be finally accepted. It has never been shown, for example, that the S. fasciata is the *only* species of mosquito capable of infecting man with yellow fever. Neither has it been definitely proved that the yellow fever parasite undergoes an evolution of 12 days' duration in the body of the stegomyia; nor can it be considered as conclusively demonstrated that the blood of the yellow fever patient is infective only during the first three days of the illness; much less can it be concluded that the yellow fever parasite must be absent from the blood after the expiry of that short period. The proofs of some at least of these points would probably not be very difficult to obtain if further experiments devised for this purpose were carried out by responsible investigators. As these points are of some importance, it is extremely desirable that such experiments should be undertaken without unnecessary delay. The fact that the specific organism of yellow fever has not been satisfactorily isolated has hitherto somewhat hindered arrival at final conclusions. There are now, however, grounds for believing that the disease is caused by a protozoal parasite, the principal forms of which have been discovered and described by Dr. Seidelin, who has found them present in the blood or tissues of about 90 per cent. of the yellow fever cases investigated by him. If these observations are confirmed by other experts a very notable advance will have been made towards the microscopical detection of the disease and the settling of many disputes as to what is, and what is not, true yellow fever, a matter often of great administrative importance. The forms of the parasite found by Dr. Seidelin have hitherto been termed "yellow fever bodies," but he now proposes to call this parasite the Paraplasma flavigenum, and he thinks it probable that it belongs to the family Babesiidæ. It is quite possible that yellow fever may not be exactly the same disease in all the places where its presence is reported; and this might be explained upon the supposition that various forms of paraplasma exist, just as there are varying types of malaria caused by different species of plasmodia. It is possible, therefore, that in the future we may have to consider different varieties of paraplasmosis in the same way that we speak of different babesioses and trypanoses. Our readers are doubtless aware that there is no recognised pathognomonic sign of yellow fever, so that at present it is often impossible to settle definitely the diagnosis of the disease. But assuming that the parasite discovered by Dr. Seidelin is the true cause of yellow fever, there would now seem to be some prospect at last of microscopical confirmation of the diagnosis being obtainable. It is admitted that these "yellow fever bodies" are commonly present in small numbers in the blood of the patients and that they may be very difficult to find unless much time is spent in searching for them. The detection of these "bodies," moreover, requires the employment of the best possible microscopic outfit. Thus it will be seen that there are still some difficulties to be surmounted before we can secure microscopical confirmation of the diagnosis of yellow fever; but further study of the subject may in time evolve an easier method of finding the specific parasite. Though Dr. Seidelin believes that the paraplasma flavigenum is the organism which causes yellow fever, he does not deny that some evidence has been brought forward connecting Sanarelli's bacillus icteroides with the disease, and he is disposed to adopt the view of Dr. J. Guiteras, who has attributed to this bacillus, along with others, responsibility for the hæmorrhagic phenomena met with in attacks of yellow fever. If this should be the case, these phenomena would have to be looked upon as complications only, and not as actual symptoms of the disease. In order that further investigations which are so much needed may be carried out at once the Yellow Fever Bureau has despatched Dr. Seidelin to Merida in Mexico, where an outbreak of yellow fever has recently occurred. If suitable opportunities are afforded to this investigator in pursuance of his inquiries we have no doubt that he will succeed in clearing up much that is at present doubtful, and at the same time obtain the further evidence which appears to be required to place the modern etiology of yellow fever beyond all dispute.

DRUG ARCHITECTURE AND THE ORGANISM.

THE chemistry of synthetic drugs is a subject of rapidly increasing importance, and the modern aspects of it are well presented in a recent volume that has reached us [1] The writer sets out a very interesting sequence of events. The question of the relationship of physiological action to chemical constitution has, of course, received considerable impetus since the introduction of synthetic remedies. The ionic theory also has advanced very considerably our knowledge of the physiological action of drugs. Pharmacology, therefore, far from being as in bygone years an empirical collection of recipes hardly deserving the name of a science, has stepped into the region of exact study. Not only are we adding every day to our means of isolating the active principles of a drug upon which certain physiological effects depend, but we are gradually becoming able to map out the constitution of these principles and to separate them into architectural groups, each possessing a significance of its own, positive or negative in character, as the case may be. It is conceivable that in the treatment of disease by drugs the time may come when structure and the pharmacology of a drug may be so well correlated as to render the practice of prescribing entirely free from empiricism. A consummation of the kind is foreshadowed in the examples given by Mr. May in his very interesting book; but against all attempts to reduce pharmacology to an exact science must be reckoned the extraordinary complication of the human machine and the consideration, further, that there are influences acting upon it which are sometimes psychological. It is doubtful whether idiosyncrasy will be brought under control by the most intimate knowledge of chemical constitution, though that reflection will not deter us from attempting to set up a pharmacological system of cause and effect. When we read in Mr. May's book paragraphs such as the following, it is obvious that the ground is being cleared in the direction indicated: "The influence of the chemical constitution of a substance on its physiological effect can be seen from the fact that definite changes in the chemical constitution of substances belonging to the same class, are usually accompanied by definite changes in the physiological effect, and, further, that the addition of certain molecular groups to differently acting substances can change them into similarly acting or equally inactive bodies." Again, "Morphine has a strong hypnotic effect, and the anchoring group is probably one of the hydroxyl groups. If these are combined with sulphuric

[1] The Chemistry of Synthetic Drugs, by Percy May, B.Sc. Lond., London, Longmans, Green, and Co., 1911, pp. 222, price 7*s.* 6*d.* net.

acid, then the morphine cannot be 'anchored' to the nerve tissues of the central nervous system and the resulting substance has no effect at all. If the hydroxyl is only altered by the entrance of an organic radicle, with the formation of substances such as methyl, ethyl, or acetyl derivatives, then the hypnotic effect is thrust into the background, while the action of the respiratory centres, produced by morphine to a slight extent, becomes much enhanced and dominates the physiological effect (codein, heroin, &c.)." As another example we may quote the following: "In many cases physiologically active compounds show a degradation of the molecule, and these same substances, if they are made so resistant that they no longer suffer any alteration in the organism, then become inactive. For example, xanthine has no tonic action on the heart muscle, but theobromine (dimethyl-xanthine) has a slight tonic action and caffeine (trimethyl-xanthine) has a still more marked tonic action, from which it will be seen that the addition of methyl groups to the nitrogen of xanthine adds a special action on the heart to the ordinary physiological action of xanthine." Mr. May's book is most interesting and suggestive, and the person who reads it carefully will not be left wondering why it is that of synthetic remedies there is no end.

THE DARK AND DAMP DAY.

HUMAN activity undoubtedly receives a check under the dispiriting conditions of the weather which has characterised the British Isles for the last week or so. The absence of direct sunlight is bad enough, but there has been also a dampness in the atmosphere which tends to interfere with the healthy functions of the skin. Normal transpiration is hindered when the air is saturated with moisture. Instead of passing away, perspired products remain as a stickiness which clogs the skin. When it is remembered that the amount of vapour passing from the skin in dry air at normal temperature may amount to 30 ounces per day, while in moist air the amount so transpired may only be from 7 to 8 ounces, it is clear that an important function is considerably hampered by excessive humid conditions. It is well known that human sweat has toxic properties, so that it is not surprising that under these meteorological conditions the vitality gets low and common ailments are prevalent. Amongst these, obscure muscular pains and chronic rheumatism are very generally complained of. The indication is in favour of increasing the application of warm water to the body so as to remove skin exhalations and compensate for the restraint put upon the skin by the continued presence of a humid air. It is, at any rate, a consolation that the absence of the feeling of well-being experienced under the present meteorological conditions is no sign of constitutional ill-health; it is a local disturbance set up by an external physical condition which arrests freedom of action. It is to be hoped that the source of this depression and disturbance, the damp and darkness of the present season, will ere long pass away.

THE ROYAL SANITARY INSTITUTE.

THE fifty-third course of lectures and demonstrations for sanitary officers will be given from January to April at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W. The course will begin on Monday, Jan. 29th, and will be continued on successive Mondays, Wednesdays, and Fridays till April 19th, at 7 P.M. The fee for the complete course of 33 lectures will be £3 3*s*., or for the first part of the course, consisting of 26 lectures on elementary physics and chemistry, public health statutes, the duties of sanitary inspectors, and municipal hygiene, £2 12*s*. 6*d*. The fee for the second part, dealing with food inspection and analysis, is £1 1*s*. Among the lecturers are the names of Dr. G. F. McCleary, Dr. Charles Porter, and Dr. E. Petronell Manby. The demonstrations include visits to municipal buildings and works, factories and dairy-farms, the Metropolitan Cattle Market, and a knacker's yard. In order to assist school teachers and other students entering for examinations in hygiene in its bearings on school life, and to help women health visitors and school nurses, a course of lectures will commence on Feb. 16th at 7 P.M. and be continued at the same hour on Mondays and Fridays during February, March, and April. The fee for the course, which includes the privilege of attending certain of the lectures given to sanitary officers, will be £1 1*s*., and the subjects treated include general physiology and personal hygiene, the growth and development of the child, the sanitation of school buildings and dwellings, educational methods, and first aid. Among the lecturers are Dr. A. B. Kingsford, Mr. F. N. K. Menzies, Mr. E. H. T. Nash, Dr. Eric Pritchard, and Mrs. Marion Hunter-Vaughan. Full particulars and forms of application for the examination can be obtained at the offices of the Institute, 90, Buckingham Palace-road, S.W.

SIR THOMAS BROWNE AND THE WITCH-TRIALS: A VINDICATION.

PERHAPS the only place where we meet the name of Sir Thomas Browne without pleasurable associations is in the account of the trial of Amy Duny and Rose Callender for witchcraft before Sir Matthew Hale in 1664. It has frequently been stated, and it is widely believed, that Sir Thomas Browne was responsible for the hanging of these two women. He made a statement in open court which is alleged to have carried great weight with the jury and to have influenced the judge against the prisoners, with the result that they were convicted and hanged. This is the view frequently adopted by writers on the subject. One of Sir Thomas Browne's biographers, Mr. Edmund Gosse, goes so far as to state that the blood of the two women was on his head. It is now suggested in two articles published in the *Norfolk Chronicle* of Dec. 23rd and 30th, 1911, that the facts connected with this trial have been greatly misrepresented, and that the suggestion that Sir Thomas Browne was responsible for the death of these two women is not in accordance with the facts of the case as recorded at the time. Mr. Malcolm Letts in the articles referred to examines the account of this incident as related by Sir Thomas Browne's most recent biographer, and compares it with the contemporary report of the trial (taken in court by the judge's marshal and published in 1682), with interesting results. It is shown that Browne had very little to do with the proceedings. He was present in court, and at an early stage he was appealed to by the judge and thereupon made a statement as to his belief in the reality of witchcraft, an expression of belief in which ninety-nine out of every hundred of his educated contemporaries would have concurred, but there is nothing more against him. It is probable that the witches were convicted on the evidence adduced by the prosecution without reference to Sir Thomas Browne's opinion. We recommend all who are interested in the great Norwich physician to read this vindication.

AT the meeting of the Ninth International Otological Congress, which is to be held in the new buildings of the medical department of Harvard University, in Boston, U.S.A., during the week beginning August 12th, 1912, the distribution of three prizes will be awarded by the International Jury to whom the adjudgment has been committed. These are the Lenval prize, the Adam Politzer prize, and the Cozzolino prize; the two former for the best published work on the anatomy, physiology, and pathology of the organ of

hearing, the latter for the best published work on the anatomy and pathology of the organ of hearing, and upon clinical therapeusis. Candidates for these prizes should communicate with the president of the jury, Professor Dr. Adam Politzer, 19, Gonzagagasse, Vienna, and should send to him the work offered in competition, at least six months before the date of the opening of the next congress. Should a sufficient number of valuable works be presented in competition it is in the power of the jury to divide the Lenval prize and the Politzer prize, thus making five prizes for award.

THE mortality from plague in India from Nov. 25th to Dec. 9th, 1911, averaged about 6800 weekly; about one-third of these deaths were in the Bombay Presidency. The actual figures for the week ending Dec. 9th were 8450 seizures and 6583 deaths. Bombay Presidency returned 2367 deaths; Madras, 284; Bengal, 231; United Provinces, 1360; the Punjab, 106; Burma, 23; Central Provinces, 557; and Mysore State, 347. There were no cases reported in Eastern Bengal and Assam. An increase in the plague mortality is reported for the week ending Dec. 16th, the total number of deaths being 8191 as against 6583 reported in the previous week. The provincial figures are: Bombay, 2509; Madras, 321; Bengal, 415; the United Provinces, 1752; the Punjab, 138; Burma, 31; the Central Provinces, 744; Coorg, 7; Mysore, 398; Hyderabad, 1505; Central India, 349; Rajputana, 22.

SANITARY MEASURES IN INDIA.

A COPY of the annual report on sanitary measures in India for the year 1909–10 (Volume XLIII.) as presented to both Houses of Parliament has reached us. It deals with the health of the European and native troops, of prisoners in jails, and of the general population, also with vaccination, medical institutions, including hospitals, dispensaries, and medical schools, with lunatic asylums, and with sanitation. The latter portion of the Blue-book is made up of an abstract of the report of the Sanitary Commissioner with the Government of India for 1909 which has already been somewhat fully reviewed in THE LANCET.[1]

Those portions of the report which relate to the incidence of sickness and mortality amongst the European and native troops, the prisoners in jails, and the general population, as well as the section on vaccination, call for no further remarks than those made in our previous notices, as no new facts are put forward, these sections of the report being on similar lines to that of the Sanitary Commissioner's report for 1909.[2]

Medical Institutions.

Section VI., dealing with medical institutions, which has been contributed by the Director-General of the Indian Medical Service, presents several interesting particulars connected with the civil hospitals and dispensaries of British India which are either entirely supported by the State or aided by local or private funds. No less than 2638 such institutions existed in 1909, an increase of 60 on the previous year. In every province there is need for more, but the lack of funds prevents a more rapid growth of medical relief. The total expenditure amounted to £781,000, an increase of £93,000 on the previous year; but the subscriptions from Indians only amounted to £40,000. The extent to which hospitals are supported by the inhabitants varies very much in different parts of the country.

In the United Provinces the pay and prospects of the civil hospital assistants have been improved and they are now called sub-assistant surgeons. It is hoped that the numerical shortage in this useful class of subordinates will now disappear. In the North-West Frontier Province difficulty still exists in attracting good assistant surgeons, hospital assistants, and compounders. The number of students belonging to this province who are undergoing medical instruction is stated to be very small, and their pay and prospects will have to be improved.

In the Central Provinces the continued prevalence of plague is said to be keeping patients away from the hospitals and dispensaries. In Madras Presidency female patients resort more freely to the hospitals every year, and the employment of trained midwives for cases of labour in the patients' own homes continues to be very popular. In Bombay Presidency the experiment of sending subordinates out into malarial districts to treat cases in their own villages was tried and will be repeated. In Burma 13 new dispensaries were opened, and there has been a marked rise in the number of cases treated. The new general hospital at Rangoon was opened and is doing good work. It is stated that arrangements have been made for an improvement in the nursing staff at headquarters hospitals and for the training of male nurses.

Lunatic Asylums.

The total number of patients of both sexes under treatment in asylums in British India for the year 1909 was 7378, as compared with 7247 for the preceding year; of these, 5883 were males and 1495 females, and they include 2019 criminal lunatics. In Bengal it is noted that the accommodation is barely adequate and the asylums show a much higher sick-rate than those of any other province. Overcrowding is recorded at Dacca and at Tezpur in the Eastern Bengal and Assam administration. In the Punjab there were increased sickness and mortality chiefly from the result of bowel complaints, the etiology of which is under investigation. The difficulty of obtaining suitable attendants is mentioned and an attempt to remedy this by employing ex-soldiers is being made. In Burma overcrowding is also reported, and extensions to the Rangoon asylum are under consideration. In Bombay Presidency the number of deaths was high—130, as compared with 86 and 67 in the previous two years. This was the result of a severe outbreak of cholera at Thana and a minor one at Poona causing 37 deaths. Madras Presidency shows an increase in the asylum population of 25 per cent. in the past decade. The total expenditure on asylums for all India and Burma for the year amounted to £77,500, of which amount £6200 were derived from paying patients.

Medical Schools and Colleges.

In Bengal, the medical college at Calcutta showed a total expenditure of £18,582, the fees received from students amounting to £3516. The average cost of education of a military student (including maintenance) is £84 and of other students £23. There were 465 male pupils, excluding 85 military pupils, and 16 female. Of these, 56 students passed the final L.M.S. or M.B. examinations, 5 military students received a diploma and entered the service, and 28 pupil nurses and 16 *dhais* (native midwives) obtained certificates. The provision of a hostel for civil students is stated to be an urgent necessity, but funds are not available. In the medical schools there was an increase in the number of students admitted to the Temple and Cuttack, but a decrease at the Campbell; 60 male students passed the final examination and 16 entered Government service. These three medical schools together cost £8411, £877 were received as fees, and 495 male and 26 female students were under instruction during the year.

In the United Provinces 258 male and 71 female students attended the medical school at Agra. Of these, 64 males and 18 females appeared for the final examination, and 46 and 13 respectively qualified. Admission to the civil class is now only open to residents of the United Provinces who hold entrance certificates of Allahabad University. In Eastern Bengal and Assam the number of students in the Berry White School at Dibrugarh and the Dacca School was 319. In Burma the medical school at Rangoon showed 28 pupils, of whom 23 receive stipends from Government. The accommodation is stated to be quite inadequate and instruction is handicapped accordingly; the students are said to be markedly below the average as compared with other schools.

In the Punjab we find that the Lahore Medical College and School showed an average number of students of 180 and 207 respectively, as compared with 204 and 193 in the previous year. The reduction in the case of the college is chiefly due to the elimination of the preliminary science classes. Fifty-four students went up for the final L.M.S. or M.B. examination and 25 passed. At the

[1] THE LANCET, May 13th (p. 1300) and 27th (p. 1446), 1911.
[2] See also THE LANCET, Dec. 2nd (p. 1576) and 9th (p. 1651), 1911.

final qualifying examination of the Lahore Medical School 33 passed out of 35 who competed. In Central India the Indore Medical School had 72 students.

In Madras Presidency the strength of the Medical College is increasing steadily. The students numbered 367; 16 passed the M.B. and 13 the L.M.S. The "refresher" courses for sub-assistant surgeons are working satisfactorily, as also are the special classes for sanitary inspectors. The chemist and druggist department is, however, stated to have proved a failure. The Prince of Wales School at Tanjore had 57 students, Royapuram 144, and Vizagapatam 42, of which 5 out of 8, 26 out of 28, and 4 passed the final examinations respectively.

In Bombay Presidency the Grant Medical College had 518 students; 89 passed the final L.M.S. out of 211 who went up. There were 25 women students. A new hostel, lecture theatre, and pathological laboratory have been opened and a physiological laboratory is under construction. At the Poona School there were 127 pupils, of whom 65 were military; at the Ahmedabad School 135 pupils, of whom 67 were military; and at Hyderabad 51 pupils. More tutors in the anatomy department are stated to be required at Ahmedabad, as the practical training in this subject is considered very defective. At Hyderabad the teaching staff consists of only the superintendent and two assistants.

This *résumé* of the medical colleges and schools of British India and Burma is of particular interest in view of the attention that has been attracted recently to the development of what has been termed the "independent medical profession" in India.

Sanitation.

Section VII. of the report deals with the subject of sanitation in the several presidencies and provinces. In Bengal the sanitary board held three meetings during the year. Among the principal subjects of discussion were the Howrah drainage scheme and the Darjeeling water-supply and sewage scheme. Excluding Calcutta, there were 128 municipalities in Bengal that spent in the aggregate 39·67 per cent. of their income on original and recurring sanitary works compared with 39·51 in 1908. The actual sums expended under the three main sanitary headings—namely, conservancy, water-supply, and drainage—were more than in 1908 by about £16,600. In Calcutta satisfactory progress is reported in the construction of the overhead reservoir at Tallah, the reinforced concrete foundations being completed in October, 1909, at a cost of £27,590. The erection of the large steel structure forming the reservoir itself, which is estimated to cost £91,367, was then commenced, and was in its last stages at the end of the year under report. The municipalities in Eastern Bengal and Assam show an increased expenditure on sanitation of nearly £13,500, due mainly to the extension of the Dacca water-supply. The Sanitary Board afforded much useful advice to Government on the numerous schemes of sanitary improvement submitted to it. A conservancy tramway was completed at Dacca, and handed over to the municipality in December, 1909, and the surface drainage of the new civil station was in progress.

Progress in sanitation in the United Provinces continues to be made, and the Sanitary Board, which met nine times during the course of the year, criticised and approved of projects for improving the sanitary conditions of municipalities at an aggregate estimated cost of over £100,000. The total expenditure incurred on sanitary works under the supervision of the sanitary engineer in 1909–10 was £46,200. In March, 1909, Dr. Gilbert Fowler, of Manchester, visited the United Provinces, and furnished a valuable report on the treatment of sullage.

In the Punjab about £28,300 were spent on water-supplies, £16,700 on drainage, and £52,650 on conservancy, road-clearing and watering, and latrines. The hydro-electric scheme for Simla was in progress, and the intramural drainage of several sections of the city of Amritsar was under construction. A valuable improvement was effected in the water-supply at Delhi by the connexion of the wells with the suction at the intake whereby clear water can be drawn from the wells when the river is in flood. In the North-West Frontier Province improvements were effected in the sanitation of Peshawar and Dera Ismail Khan. The municipalities in the Central Provinces spent 46 per cent. of their income on sanitary works. Improvements in the water-works at Nagpur were in progress, and the extension of the water-supply at Harda at an estimated cost of £80,000 was proceeding.

In Madras Presidency £40,880 were spent on water-supplies, £5747 on drainage, and £63,515 on conservancy, including the upkeep of roads, &c. Designs and plans for new works for the main drainage of Madras city, estimated to cost £107,307, were completed. In Bombay Presidency, excluding the city of Bombay, £126,716 were spent on the improvements of water-supplies, drainage, and conservancy. Estimates amounting to £23,633 and £19,733 for water-supply schemes at Nasik and Hyderabad respectively were sanctioned and the works begun. The Pundharpur water-supply was completed, and the distribution of the water-supply at Karachi was extended and the drainage works of that city continued. In Bombay city the works in connexion with the Malabar Hill sectional sewerage scheme were completed during the year. In Burma, £107,994 were spent on water-supplies, £87,459 on conservancy, £41,047 on drainage, and £79,179 on other sanitary works.

The Vacant Post of Sanitary Commissioner.

Since the issue of the report of sanitary measures in India, 1908–09, it has been our sad duty to chronicle the sudden death of Lieutenant-Colonel J. T. W. Leslie, C.I.E., I.M.S., Sanitary Commissioner with the Government of India, in March, 1911. Since this distinguished officer's death the duties of Sanitary Commissioner have been carried on by the Director-General of the Indian Medical Service at the instigation of the Government of India with a view to financial economy in saving the salary of this appointment. In THE LANCET of July 29th, 1911, p. 308, we added a word of warning and protest against this short-sighted policy, which we ventured to remark would be a retrograde one. Since then we are glad to record that the Secretary of State for India, in replying to Lord Curzon in the House of Lords in November, stated that, contrary to the proposal of the Government of India, but in agreement with the views of the Indian Council, he considered that it was desirable to retain the appointment. We stated in THE LANCET of Dec. 30th, 1911, p. 1868, that we felt that Lord Crewe came to the right decision in this matter. There is no doubt, and no one denies, that economy must be practised and that appointments which are not necessary must be abolished; but over and over again it has been shown that expenditure on prevention of disease really results in economy, and unless this department of research is directly represented at headquarters of Government there is danger that due consideration will not be given to its requirements. Up to the present no further official action has been made public, and we sincerely hope that the Government of India will no longer delay its selection and fill the vacancy by appointing a whole-time officer of the Indian Medical Service.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

West Riding of Yorkshire.—This county, with a population of about 1½ millions, comprises as many as 129 urban and 29 rural sanitary districts. Many of the former are "urban" only in name and illustrate the frequent fallacy of assuming that urban districts and towns are synonymous. Eight of them have not so much as 1000 inhabitants, while many have a large area. The urban district of Rishworth, for example, with a population of only 933, is 6551 acres in extent. When consideration is given on the one hand to the nature and limited resources of many of these districts and the small sums which are available for payment of their sanitary officers, and on the other hand to the demands of modern legislation and of Government departments on medical officers of health, it will be seen that it is only by the active participation of the county authorities that public health work can be made at all possible. Dr. J. R. Kaye's report, as usual, shows that much is done in this direction by the department under his charge. Among useful practices for this purpose the county inspections of isolation hospitals and the "nursing exchange" may be mentioned. A county scheme was formulated for a central sanatorium for pulmonary tuberculosis near Pateley Bridge to which different sanitary authorities in the county would contribute. Many authorities refused to participate, but sufficient support was forthcoming to enable the scheme to be pursued. Like all similar schemes, however, it has been suspended until the

distribution of funds under the National Insurance Act has been determined on. Meanwhile fever hospitals are being utilised to a limited extent for tuberculosis in various parts of the county. Stress is laid in the report on the active policy of dealing with bovine tuberculosis which has been followed in the county, and its justification in view of the findings of the Royal Commission. The county authorities examine milk samples for tubercle bacilli, but Dr. Kaye rightly insists on the danger of relying upon sampling milk, as if for the detection of adulteration, where tuberculosis is concerned. Time is necessary for guinea-pig inoculation, and where the result is positive it is often found that no data are available by which to identify the cow or herd which is at fault. To utilise bacteriological testing in the best way veterinary inspection is essential, the samples taken being of known origin and collected for specified reasons. So many instances of poisoning, due to the action of moorland waters on lead, were formerly to be traced in the county, that it is satisfactory to find that the known cases in 1910 were very few, and that practically all the public water-supplies yielding acid water are now subjected to neutralising treatment with more or less satisfactory results. In regard to housing Dr. Kaye refers to several "model villages" which owe their origin to the voluntary action of owners who have laid out their land on a regular system. In competition with any such scheme, however, it is open to any neighbouring owners to build on an entirely different and incompatible arrangement, and the jerry-builder can easily put up houses in the vicinity and reap a considerable advantage over the promoters of the "garden city" by reason of his freedom from the costlier restrictions. Some remedy for this is to be looked for under the town-planning part of the Housing Act of 1909; but, as Dr. Kaye observes, all available land in the South Yorkshire coal-field cannot be scheduled. The procedure under the Act is complicated and slow, and it is to be feared that the proper opportunities are being missed in many districts. In the case of insanitary houses Dr. Kaye refers to the onerous duties placed on medical officers of health under the housing regulations, and the impossibility of systematic inspection being carried out on any reasonable scale in districts where the officers who have to work the Act—the medical officer of health and the sanitary inspector—have neither the time nor the pay which are essential. This consideration is emphasised by many county medical officers of health in recent reports which have come to our notice, and must soon be taken seriously by the central departments concerned if the latest of our housing Acts, of which so much was expected, is to produce, outside large municipalities, any more satisfactory results than its predecessors.

County of Devon.—A "Devonshire stock" is associated with many fine traditions and good physical qualities, and we note with regret a birth-rate in the administrative county which has now fallen to 19·2—or 2 per 1000 less than in 1901. The low figure, as compared with England and Wales as a whole, is no doubt to be connected with the number of elderly people who live at the seaside and health resorts of the county, but there seems to be a very definite fall in the births among the indigenous population. It is clear that an insufficient and unsuitable supply of working-class dwellings contributes materially to this decrease. "The cry still comes from the rural districts concerning the lack of new houses, and the unsatisfactory condition of the old cottages in regard to ventilation, floors, dampness, insufficient window space, and bedroom accommodation." A useful diagram in Mr. G. Adkins's report shows some very marked differences in the tuberculosis death-rate between the several districts in the county, and it is to be hoped that with the advent of notification the circumstances associated with these differences will be further studied. The urban district of Torrington, with a tuberculosis death-rate of 2·7 per 1000, stands high in the list, as was the case in previous years. Personal instruction and advice on the prevention of the disease have been given by the education committee of the county through school lessons and lantern lectures by medical inspectors and agricultural lecturers, and Mr. Adkins anticipates good results from these and similar measures which have been adopted in many places in the county. The report discusses the water-supplies of the different districts, and enumerates a large number of cases in which a new supply or alteration of the existing works is imperative. Many of the summer visitors whose advent does so much for the prosperity of some of these Devonshire villages would welcome an active policy by the local authorities in this and in other respects—notably the provision of hospitals for infectious disease and improved arrangements for removal of refuse—in which this report shows that great deficiency often exists.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8745 births and 5172 deaths were registered during the week ending Jan. 13th The annual rate of mortality in the large towns, which had declined from 16·4 to 15·3 in the four preceding weeks, was equal to 15·4 per 1000 last week. During the 13 weeks of the fourth quarter of last year, the mean annual rate of mortality in the 77 large English towns averaged 14·7 per 1000, and was 0·4 per 1000 in excess of the death-rate recorded in London during the same period. The annual death-rates in the several towns ranged from 4·7 in Southend-on-Sea, 8·1 in Swindon, 8·3 in Wimbledon, 8·6 in Hastings, and 8·9 in Walthamstow, to 22·4 in Dewsbury, 22·6 in Stoke-on-Trent, 23·2 in Halifax, 25·9 in Stockton-on-Tees, and 32·6 in Walsall.

The 5172 deaths from all causes in the 94 towns were 20 in excess of the number recorded in the previous week, and included 323 which were referred to the principal epidemic diseases, against 313 in the previous week. These 323 deaths from the principal epidemic diseases included 88 which resulted from whooping-cough, 69 from measles, 69 from diphtheria, 58 from infantile diarrhœa, 20 from enteric fever, and 19 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·0, or 0·1 per 1000 in excess of that recorded in the previous week. The highest annual death-rates per 1000 persons living from measles were 1·4 in Nottingham and in Oldham, 1·9 in Burnley, and 3·6 in Warrington; from whooping-cough, 1·1 in St. Helens and in Cardiff, 1·2 in Newport (Mon.), 1·8 in Bury, 1·9 in Merthyr Tydfil, 2·4 in West Hartlepool, and 4·5 in Walsall; and from infantile diarrhœal diseases, 1·5 in Stoke-on-Trent. The 69 deaths attributed to diphtheria, which were 20 in excess of the number in the previous week, included 18 in London and its suburban districts, 6 in Liverpool, 5 in Leeds, 4 in Norwich, 4 in Bradford, and 3 each in Gillingham, in Plymouth, and in Newcastle-on-Tyne.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had continuously decreased from 2213 to 1845 in the eight preceding weeks, had further declined to 1762 on Saturday last; 165 new cases of this disease were admitted to these institutions during the week, against 182, 162, and 193 in the three preceding weeks. These hospitals also contained on Saturday last 1242 cases of diphtheria, 276 of whooping-cough, 116 of measles, and 52 of enteric fever, but not one of small-pox. The 1259 deaths from all causes in London were 88 fewer than the number in the previous week, and were equal to an annual death-rate of 14·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 332 and 382 in the two preceding weeks, declined to 290 last week, and were 1 fewer than the number registered in the corresponding week of last year.

Of the 5172 deaths in the 94 large towns last week 220 were attributed to different forms of violence, and 449 were the subject of coroners' inquests. The causes of 50, or 1·0 per cent., of the deaths registered in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and its 14 suburban districts, Leeds, Bristol, Bradford, Nottingham, Portsmouth, Salford, Leicester, and in 45 other smaller towns. The 50 uncertified causes of death last week included 9 in Birmingham, 7 in Liverpool, 4 in Darlington, and 3 in Manchester.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns having an estimated population of 2,182,400 persons in the middle of this year, 1111 births and 781 deaths were registered during the week

ending Jan. 13th. The annual rate of mortality in these towns last week was equal to 18·7 per 1000, and was 3 3 per 1000 above that recorded in the 94 English towns. During the fourth quarter of last year the mean annual death-rate in the former eight Scotch towns averaged 16 9 per 1000, or 2·2 per 1000 above that which obtained in the 77 English towns during the same period. The annual death-rates in the several Scotch towns last week ranged from 11·4 in Partick, 12·0 in Kilmarnock, and 12·3 in Paisley, to 20 6 in Greenock, 21·1 in Glasgow, and 21·9 in Aberdeen.

The 781 deaths from all causes in the 18 Scotch towns were 76 in excess of the number in the previous week, and included 82 which were referred to the principal epidemic diseases, against 83 in the previous week. Of these 82 deaths, 41 resulted from measles, 12 from whooping-cough, 10 from diphtheria, 10 from infantile diarrhœal diseases, 6 from scarlet fever, and 3 from enteric fever, but not one from small-pox. These 82 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·0 per 1000, or 1·0 per 1000 above that recorded in the 94 English towns. The 41 deaths attributed to measles were 7 in excess of the number returned in the previous week, and included 23 in Glasgow, 8 in Aberdeen, and 5 in Edinburgh. Of the 10 fatal cases of diphtheria, 3 were registered in Glasgow, 3 in Edinburgh, and 3 in Aberdeen.

The deaths referred to diseases of the respiratory system in the 18 towns numbered 147, and were 13 in excess of the number in the previous week; and 30 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 683 births and 450 deaths were registered during the week ending Jan. 13th. The annual rate of mortality in these towns, which had been 18·0 and 18·6 in the two preceding weeks, further rose to 20·3 per 1000 in the week under notice. During the 13 weeks of the fourth quarter of last year the mean annual rate of mortality in these Irish towns averaged 18·4 per 1000; in the 77 English towns during the same period the mean annual death-rate did not exceed 14·7 per 1000, while in the eight Scotch towns it was equal to 16·9 The annual death-rates last week in the several Irish towns were equal to 20 7 in Dublin (against 14·5 in London), 19·5 in Belfast, 25 2 in Cork, 16 6 in Londonderry, 14·9 in Limerick, and 19·0 in Waterford; while in the 16 smallest of these Irish towns the death-rate was equal to 21·3 per 1000.

The 450 deaths from all causes in the 22 Irish towns were 37 in excess of the number in the previous week, and included 28 which were referred to the principal epidemic diseases, against numbers decreasing from 39 to 29 in the three preceding weeks; of these 28 deaths, 11 resulted from whooping-cough, 5 from measles, 4 from diarrhœal diseases, 3 from diphtheria, 2 from enteric fever, 2 from scarlet fever, and 1 from typhus, but not one from small-pox. These 28 deaths from the principal epidemic diseases were equal to an annual rate of 1·3 per 1000; the death-rate from these diseases last week did not exceed 1·0 in the 94 English towns, while in the 18 Scotch towns it was equal to 2·0 per 1000. The deaths attributed to whooping cough, which had declined from 16 to 4 in the three preceding weeks, rose to 11 last week, and included 6 in Belfast and 3 in Dublin. Of the 5 deaths referred to measles, which were equal to the average in the two preceding weeks, 3 were registered in Dublin. The 4 fatal cases of diarrhœa included 2 of infants under two years of age. The 3 deaths from diphtheria and the 2 fatal cases of scarlet fever occurred in Dublin. The 2 deaths from enteric fever were registered in Dublin and Limerick respectively, and that from typhus in Belfast.

The deaths referred to diseases of the respiratory system, which had been 85 and 99 in the two preceding weeks, further rose to 109 last week. Of the 450 deaths from all causes in the 22 Irish towns, 141, or 31 per cent., were recorded in public institutions, and 11 were attributed to different forms of violence. The causes of 10, or 2·2 per cent., of the total deaths in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 English towns the proportion of uncertified causes of death last week did not exceed 1·0 per cent.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 6·3 per 1000 of the population, estimated at 4,522,628 persons in the middle of last year. In the three preceding months the rates were 6·9, 8·5, and 7·8 per 1000 respectively. The lowest rates last month were recorded in Chelsea, Holborn, the City of London, Shoreditch, Stepney, and Southwark; and the highest rates in Hackney, Bethnal Green, Deptford, Greenwich, Lewisham, and Woolwich. The prevalence of scarlet fever again showed a decline last month from that recorded in other recent months; the greatest proportional prevalence of this disease last month was recorded in St. Marylebone, Hackney, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 1878 scarlet fever patients at the end of December, against 2152 and 2103 at the end of the two preceding months; the weekly admissions averaged 198, against 261, 317, and 254 in the three preceding months. Diphtheria was much less prevalent than it had been in either of the two preceding months; among the several boroughs the greatest proportional prevalence of this disease last month was recorded in Paddington, Hammersmith, Hampstead, the City of London, Wandsworth, Greenwich, Lewisham, and Woolwich. There were 1294 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 1143 and 1327 at the end of the two preceding months; the weekly admissions averaged 141, against 168 and 180 in the two preceding months. The prevalence of enteric fever also showed a marked decrease in December, as compared with that in the first and second months of the quarter; this disease was proportionally most prevalent last month in Paddington, Kensington, the City of Westminster, Bethnal Green, Stepney, Poplar, Bermondsey, and Lewisham. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 160 and 85 at the end of the two preceding months, had declined to 76 at the end of last month; the weekly admissions averaged 35, against 90 and 46 in the two preceding months. Erysipelas was proportionally most prevalent in Hammersmith, St. Pancras, Hackney, Finsbury, Shoreditch, Bethnal Green, Southwark, Battersea, Deptford, and Greenwich. The 29 cases of puerperal fever notified during the month included 5 in Stepney, 4 in St. Pancras, 3 in Lambeth, and 2 each in Kensington, Fulham, Islington, Hackney, and Battersea. Six cases of cerebro-spinal meningitis and 6 of poliomyelitis were notified during the month.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the four weeks ending Dec. 30th the deaths of 5314 London residents were registered, equal to an annual rate of 16·1 per 1000; in the three preceding months the rates had been 16·8, 15·1, and 14·1 per 1000 respectively. The death-rates last month ranged from 10·8 in Hampstead, 12 9 in Stoke Newington, 13·1 in Wandsworth and in Lewisham, 13·3 in Chelsea, and 13·8 in Woolwich, to 19·3 in Southwark, 19 5 in Shoreditch, 19·7 in Deptford, 20·6 in Finsbury and in the City of London, 22·0 in Greenwich, and 24·0 in Holborn. The 5314 deaths from all causes included 50 from measles, 13 from scarlet fever, 61 from diphtheria, 37 from whooping-cough, 12 from enteric fever, and 63 among children under two years of age from diarrhœa and enteritis. The lowest death-rates from these diseases in the aggregate were recorded in Fulham, Chelsea, the City of Westminster, St. Marylebone, and Woolwich; and the highest rates in Holborn, Shoreditch, Poplar, Southwark, Deptford, and Greenwich. The 50 deaths from measles were only one-third of the corrected average number in the corresponding period of the five preceding years; 15 belonged to Deptford, 12 to Greenwich, 4 to Paddington, 4 to Lambeth, 3 to

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1911.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

Southwark, 3 to Camberwell, 2 to Bethnal Green, and 2 to Bermondsey. The 13 fatal cases of scarlet fever were also equal to only one-third of the corrected average number; of these 13 deaths, 2 belonged to Wandsworth and 1 to each of eleven other boroughs. The 61 deaths from diphtheria slightly exceeded the corrected average number, and included 8 in Islington, 5 in Lambeth, and 4 each in St. Pancras, Hackney, Shoreditch, and Poplar. The 37 fatal cases of whooping-cough were 31 fewer than the corrected average number; of these 7 belonged to Southwark, 6 to Poplar, 5 to Lambeth, 4 to Stepney, and 4 to Deptford. The 12 deaths from enteric fever, of which 2 belonged to Poplar, showed a decline of 7 from the corrected average number. The greatest proportional mortality from diarrhœa and enteritis among children under two years of age was recorded last month in St. Pancras, Shoreditch, Stepney, Lambeth, Battersea, and Wandsworth. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was nearly 49 per cent. below the average.

THE SERVICES.

Royal Army Medical Corps.

Colonel M. W. Kerin, C B., principal medical officer of the Seventh (Meerut) Division, has joined at Meerut Cantonment from Mussooree. Lieutenant-Colonel C. Birt has been appointed a Member of the Army Medical Advisory Board as Expert in Tropical Diseases, vice Colonel Sir David Bruce. Lieutenant-Colonel M. L. Hearn, senior medical officer, Ceylon, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel R. L. R Macleod has arrived home from India on completion of his tour of foreign service. Lieutenant-Colonel S. Westcott, C.M.G., lately commanding the station hospital at Chakrata, has been appointed in charge of the Military Hospital at Edinburgh. Lieutenant-Colonel S. Hickson has arrived home from Wynberg. Lieutenant-Colonel T. B. Winter has taken over charge of the Military Hospital at Colchester and command of No. 9 Company, Royal Army Medical Corps. Lieutenant-Colonel F. J. Morgan has been detailed for duty on board the transport s.s. *Plassy* leaving Bombay for Southamptom on March 13th. Lieutenant-Colonel C. C. Reilly has been placed under orders for a tour of service with the Southern Army in India, and on arrival will be appointed to command the Station Hospital at Colaba.

Major F. S. Irvine has been selected to succeed Brevet-Lieutenant-Colonel A. P. Blenkinsop as Assistant Commandant at the Royal Army Medical College, London. Major A. C. Fox has been ordered to join the Irish Command on Feb. 1st, and on arrival will be appointed to the Dublin District for duty. Major W. Hallaran, from Jhansi, has taken over charge of the Station Hospital at Chakrata. Major G. S. McLoughlin, D.S.O., has been selected to hold charge of the Military Hospital, Golden Hill. Major M. Boyle has been posted to Jersey for duty. Major C. S. Smith, from Mullingar, has been placed under orders to embark for a tour of service in India. Major J. C. Jameson has been appointed in charge of the Surgical Division at the Royal Herbert Hospital, Woolwich. Major C. W. H. Whitestone has been transferred from Cherat to Peshawar as Staff Officer of Medical Mobilisation Stores. Major F. J. W. Porter, D.S.O., has taken up duty at Reading. Major H. B. Fawcus has been taken on the strength of the London District on taking up the appointment of Assistant Professor of Hygiene at the Royal Army Medical College, in succession to Major C. F. Wanhill, placed under orders for a tour of service in India. Major J. M. Cuthbert, from Edinburgh, has taken up duty at Leith. Major J. Cowan has been placed under orders to embark for India on Feb. 29th. Major A. J. MacDougall, from Ceylon, has been appointed for duty in the Belfast District.

Captain H. C. Sidgwick, from Jamaica, has been posted to the London District. Captain R. H. MacNichol has taken up duty at the Royal Herbert Hospital, Woolwich, as Specialist in Dermatology and Venereal Diseases. Captain H. T. Stack, serving at Belfast, has been placed under orders to embark for a tour of service in India. Captain V. T. Carruthers has been placed under orders to join the Cork District on Jan. 19th. Captain O. Ievers, from Wynberg, has been appointed to Dublin for duty. Captain F. E. Rowan-Robinson, from Norwich, has embarked for a tour of service in Bermuda. Captain W. C. Nimmo, in charge of the Cantonment General Hospital at Chakrata, has been detailed for duty on board the transport s.s. *Plassy*, which left Bombay for Southampton on Jan. 11th. Captain H. L. Howell, in charge of the Brigade Research Laboratory at Ahmednagar, has been granted eight months' leave of absence home from India. Captain E. W. Powell, from Aden, has been appointed to Cork district for duty. Captain V. H. Symons, from Bloemfontein, has taken up duty at Belfast. Captain A. H. Jacob has been transferred from the Second (Rawal Pindi) Division to the Third (Lahore) Division. Captain W. Egan, from Rangoon, has been granted eight months' leave of absence, with permission to revert to the Home Establishment on expiration thereof.

Lieutenant H. Gall has been transferred from Simla to Ambala for duty at the Station Hospital. Lieutenant O. W. McSheehy and Lieutenant H. F. Joynt have embarked for a tour of service in South Africa. Lieutenant T. J. Hallinan, from Cork, has taken up duty in the Dublin District. Lieutenant J. Gilmour, from Devonport, has taken up special duty under the Foreign Office.

Indian Medical Service.

Colonel F. C. Reeves has arrived home on leave of absence from India. Colonel H. Hendley, principal medical officer of the Sirhind and Jullundur Brigades, Third (Lahore) Division, has taken up duty at Army Headquarters, Simla, as Deputy Principal Medical Officer, His Majesty's Forces in India. Lieutenant-Colonel J. Penny, Bengal Presidency, has returned to India on completion of his furlough. The services of Major W. E. McKechnie have been placed at the permanent disposal of the Government of the United Provinces. Major D. H. F. Cowan has taken up duty as Civil Surgeon at Shahpur. Major C. R. Pearse has been appointed Civil Surgeon at Maymyo during the absence on special military duty of Lieutenant-Colonel A. O. Evans. The services of Major N. P. O'Gorman Lalor have been placed permanently at the disposal of the Government of Burma for employment in the Civil Medical Department. Major C. B. Prall, superintendent of the Central Prison at Bareilly, has been granted 11 months' leave of absence home from India. Major S. Anderson has been permitted to extend his furlough. Major J. Mulvany, on return from leave, has been appointed Superintendent of the Central Jail at Kalighat, Calcutta. Major C. Hudson has been granted 18 months' furlough home from India.

Captain R. T. Wells, officiating civil surgeon at Dera Ghazi Khan, has been appointed Plague Medical Officer at Rohtak, in succession to Captain S. B. Mehta, whose services have been placed at the disposal of the Government of India, Department of Education. Captain S. H. Lee-Abbott, civil surgeon at Dalhousie, has been selected for appointment as Civil Surgeon at Ferozepore. Captain W. W. Jeudwine, officiating civil surgeon at Multan, has taken up duty as Plague Medical Officer at Rawal Pindi. Captain D. N. Anderson has arrived home on leave of absence from India. Captain J. A. Cruikshank has been appointed to the Bacteriological Department and his services placed temporarily at the disposal of the Madras Government. Captain G. C. L. Kerans has taken up duty as Specialist in Ophthalmology to the Eighth (Lucknow) Division. Captain W. D. A. Keys has been appointed to officiate as Civil Surgeon at Karwar. Captain F. W. Sumner, officiating civil surgeon at Shahjahanpur, has been transferred to Fategarh. Captain G. S. Husband has been attached to the Jail Department in the Punjab. Captain J. C. G. Kunhart has been appointed permanently to the Bacteriological Department.

Lieutenant A. L. Sheppard has been appointed to the medical charge of the 122nd Rajputana Infantry. Lieutenant V. P. Norman has arrived home on leave of absence from India. Lieutenant K. K. Mukerji has been appointed Specialist in the Prevention of Disease at Kohat. Lieutenant J. H. T. Morgan has taken up duty at Cawnpore as Officiating Medical Officer to the 9th Hodson's Horse during the absence of Captain C. W. F. Melville, who is on active service with the Abor expedition on the North-East Frontier.

Scale of Fees for Professional Services by Medical Officers in India.

Revised regulations have been promulgated by the Home Department of the Government of India regarding the scale

of fees for professional services to native chiefs and Indian nobles to be charged by medical officers of Government. The following are the more important clauses :—1. An officer is entitled to demand or receive such fees as may be arranged between himself and the person employing him, provided that he does not without the special permission of the local Government, obtained as provided below, demand or receive in addition to his travelling expenses a higher fee than Rs. 500 (£33 6*s.* 8*d.*) a day for the first three days and Rs. 250 (£16 13*s.* 4*d*) a day thereafter, the full daily fee being given for every complete period of 24 hours' absence with a proportionate fee for periods of less than 24 hours. 2. For similar attendance not involving absence from his headquarters a medical officer may demand or receive fees in accordance with the scale which he has fixed for his patients generally. 3 Before accepting or demanding from a ruling chief or Indians of position as referred to in Rule 1 a fee in excess of the rates laid down in Rules 1 and 2 above, a medical officer must report the case confidentially to the local administrative medical officer, who will obtain unofficially and communicate to him the orders of the local Government. When taking the orders of Government the administrative medical officer will be careful not to disclose any of the medical particulars of the case. 4. Local Governments and administrations shall have full power to dispose of all cases so reported to them, but shall be at liberty to consult the Director-General, Indian Medical Service, or to refer any particular case for the orders of the Government of India. 5. Fees for operations and confinements may be accepted equal in amount to those current in similar circumstances in the profession in the United Kingdom. The above revised rules are stated to cancel the Home Department Notification No. 100, dated Feb. 2nd, 1911.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on Jan. 9th, Sir W. Graham Greene, K.C.B , in the chair, the sum of £45 was distributed among the several applicants.

Correspondence.

"Audi alteram partem."

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—Dr. Lauriston E. Shaw, both in his letter to you and in sundry other letters to the *Times*, makes abundantly clear his personal approval of the National Insurance Act. To him and to the majority of the executive of the British Medical Association this Act appears commendable, and its medical arrangement, after all, not so bad. From those who are of that opinion it is not surprising to have the sort of extenuations and apologies put forward that constantly appear in their letters and speeches. Dr. Shaw cannot agree with Sir Alfred Pearce Gould as to the demerits of "contract practice"; and looking at his reasons it is not probable that it would be possible to prove to him that, nevertheless, Sir Alfred Pearce Gould's view is correct, and held by the great majority of the medical practitioners of the country. The latter are not likely to be converted to Dr. Shaw's opinion by the kind of reasoning he seems to delight in: even if they admit that "this principle of payment"—viz., the payment for work done—is absent from the army, the navy, and even if Cabinet ministers scout the payment by fee. I might even add that if Dr. Shaw were to affirm that he himself, if he had his choice, would prefer to be paid by contract, it would not alter their opinion on this point. It may, no doubt, be said *per contra*, that I, and others like me, to whom this Act does not appear commendable, and who regard its medical proposals as bad as they well could be, on our part attack the Act in the same unscrupulous manner as they defend it. I do not think so. Most of us waited loyally till the Bill became an Act; till it was possible to see how far the executive of the Association was able to modify or remove what was almost universally condemned by the whole profession. But now the Act is an accomplished fact, and it is left to the profession to say whether it is satisfied with what has been done, and to decide—without law breaking—whether it will accept or reject the medical duties offered to it. It seems to me the duty of every practitioner to make up his mind which of the two alternatives he is going to choose. The opponents of this Act may be pessimistic, but they interpret its provisions in their ordinary grammatical sense. Above all, they are not so prone to confound *possibilities* with *probabilities*. No doubt, the loose and slovenly drafting of the Act might justify illimitable possibilities, and might grant the profession terms that all might approve of. Indeed, the Commissioners might make quite another Act of it. Well, let us wait and see! This has been called by some the "policy of doing nothing," the "policy of running away," &c. Let us rather call it the policy of "masterly inactivity," waiting to see what our opponents are going to do. In spite of Dr. J. H. Taylor's terrible warning against letting slip the doles ear-marked to us by the provisions of the Act, even if the present condition of medical practice in this country were prolonged for a considerable time longer, as a general practitioner of some years' standing I cannot help thinking that it would be far better to follow the advice of Sir Alfred Pearce Gould and Sir Clifford Allbutt, and even of Dr. F. J. Smith, than be led away by the optimistic and, in my opinion, misleading generalisations of Dr. Shaw and other favourers of this latest outcome of modern democracy.—I am, Sir, yours faithfully,

Jan. 13th, 1912. MAJOR GREENWOOD.

To the Editor of THE LANCET.

SIR,—It would almost appear ungracious on my part, being myself only a guest and not a member of the British Medical Association, to play the part of critic of the proceedings of the new organisation—the Reform Committee—which it was attempted to launch on the medical world at a meeting held last Tuesday, Jan. 9th, at the Hammersmith Town-hall, yet I would contend that it is not only right, but almost a duty, to watch the progress of, and discuss the effects of, any serious movement by any section of the medical profession which would vitally affect the fortunes and interests of us all, both individually and collectively, as the movement there initiated. I make no apology, therefore, for expressing my impressions as an outsider of the meeting, and of what I imagine will be the result. The old motto, "Audi alteram partem," seemed to form no part of the programme of the meeting, and the noisy and by no means pertinent interruptions which greeted expressions of opinion adverse to the scheme must have disappointed, if not disgusted, many of those who looked on at the proceedings from a comparatively dispassionate point of view.

Now as to the possible results of this new revolutionary venture. How is it going to affect the profession? Is it going to bring us any nearer to the attainment of the six cardinal points on which the profession is practically united? It must be remembered there exists a large body of medical men who have not been, or have ceased from various causes to be, members of the British Medical Association. We have been, for the sake of unity, content to let that body assume, as the largest organised body in the medical profession, the rôle of negotiator or bargainer with Mr. Lloyd George in regard to the demands of the profession. Such meetings as took place last Tuesday cannot but help disillusion us of the wisdom of this step, for the more we hear and know of the history of the bargaining that went on, the more we feel convinced that those whom in our innocence we trusted sold our birthright for the proverbial mess of pottage, the more we feel that the reasonable demands of the profession were sacrificed on the altar of political expediency!

It matters little now that the feeling of betrayal is seizing on the members of the Association, and that they wish to turn and rend those who had the direction of the negotiations—viz., the Council of the Association. What we poor practitioners now want, and vainly hoped would be given at the meeting to which we were invited, was a straight lead how to connect up the broken strands of the negotiation where it was broken by Mr. Lloyd George when he informed the Council that most of our reasonable demands could not be inserted into the Bill. What we want now is not

recriminations, but what is the best course under the circumstance to pursue in order to obtain them, and thus be able in as efficient manner as possible to administer to the sick and poor the medical benefit which the originator of the Bill had in his mind. It may be worth while reminding my readers that Mr. Lloyd George stated as one of the chief attractions of his Insurance Bill that he was offering to the insured "good doctoring without doctors' bills" (and, by the way, without coming to terms with the doctors). Now, to my mind "good" doctoring can only be obtained as the result of mutual confidence between doctor and patient—confidence on the part of the patient that he is receiving the best of attention and skill, confidence on the part of the doctor that he is receiving fair and adequate remuneration for services rendered. No system can possibly be good, or can supply a good article, that does not meet these requirements. The doctors laid down six demands as the minimum with which they would be satisfied; the Bill has been passed and the profession's minimum has not been satisfied. To my mind it is as important to the insured as to the doctors that the bargain should be a complete one; how otherwise are they to expect "good" doctoring?

Now I went to the meeting on Tuesday, as I have before remarked, hoping that some course might be devised by which the demands of the profession might have been satisfied. I wanted bread and was offered a stone. The stone was to turn out the Council of the British Medical Association and attempt to induce Mr. Lloyd George to introduce an amending Bill which would include the unsatisfied demands of the profession. What a chimera! What fatuity! Mr. Lloyd George already sees by such meetings as these that the members of the medical profession are already cutting one another's throats, sees that he has only to wait and watch, and the profession will eventually, like the Kilkenny cats, murder one another, and lie, a victim to suicide, in the hollow of his hand. Distrust, disunion, is playing his game; the want of unity, of solidarity, of cohesion, is playing havoc with any chance we have of united action, and hope deferred of a united profession is making the heart of the poor humble practitioner sick. By such meetings as were held on Tuesday we are not likely to be any "forrader," and recrimination is no remedy. We poor practitioners want unity, unity, and again unity; for union alone makes strength.—I am, Sir, yours faithfully,

RICHARD BEVAN, L.R.C.P. Lond., D.P.H.

Girdlers'-road, Brook Green, Jan. 15th, 1912.

THE MORBID DIATHESES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 6th Sir Dyce Duckworth, who honoured me by attending my Bradshaw lecture, writes with his usual courtesy in defence of the Morbid Diatheses, which I maintained were gradually disappearing under modern investigation, that had proved various diseases formerly believed to be of constitutional origin to depend on the inroads of external pathogenetic microbes. I could but feel as I was lecturing that I was treading with elephantine weight on many of his inoffensive pedal digits, and I was, therefore, the more gratified to receive from him a cordial appreciation of my lecture, with many points in which I felt sure he was not in agreement.

In the letter addressed to you Sir Dyce Duckworth states that my views on the medical diatheses, though "rather startling," he had reason to believe were shared by "the younger pathologists and surgeons." In this I am inclined to think he is correct; but he goes on to depreciate, in a manner I never dreamed of, the workers of the past or passing generation. "The older physicians are to be regarded as rather unwise men with feeble powers of observation" is a sentence which there is nothing in my lecture to warrant. On the contrary, I spoke of "the giants in observation" who were misled by a predominant theory. I do not deny the influence of *soil*, but I deny that it is essentially a family product, or that it is of "equal importance" with the *seed*, as Sir Dyce Duckworth terms the invading microbes.

To illustrate my position, I will mention a case that was brought under my notice as recently as Saturday last. The head fettler on a local railway, a very strong man, with a healthy wife and a family of five, left his cottage two or three years ago for a larger one, in which the previous occupant and his sister had died from phthisis. Soon after, his second son, a boy of 15 years, was noticed to be ailing and he is now in an advanced incurable stage of consumption. Thus a family, all of whom were previously healthy, by entering an infected cottage were subjected to a tubercular test which picked out the weakest.

I am, Sir, yours faithfully,

Jan. 16th, 1912. R. CLEMENT LUCAS.

To the Editor of THE LANCET.

SIR,—Amidst the many and complex problems of present-day views of mental and physical disease we are not very much nearer the truth than were our forefathers. Certainly, advancing strides have brought about important changes in the line of treatment, but are these not constantly changing in detail? Everyone has some part of his mental or physical side defective. It is our duty to search out these defects on experimental principles and provide a suitable environment. And if we observe closely the environment of the insane, and not least the feeble-minded, we shall recognise progression. Given any pattern of mind and body a suitable environment can invariably be found. It is interesting to note, too, that institutional care and management of mental cripples is preventive of appendicitis. That is to say, it is a physical disease very rarely seen in asylums. But we have no proof that the cæcum and its appendix, nay, the intestinal tract, is of a superior build among the insane than is to be found outside asylum environment.

I am, Sir, yours faithfully,

Alton, Hants, Jan. 12th 1912. JOHN FREDK BRISCOE.

UNICELLULA CANCRI.

To the Editor of THE LANCET.

SIR,—In the two lectures given by Sir Henry Butlin, and which appeared *in extenso* in THE LANCET of Nov. 25th and Dec. 2nd, 1911, the author leads up to the conclusions that the cancer cell is derived from, and in a general way inherits the morphology of, the cells of the part in which it takes its origin; that the "vital difference" between it and the normal cell is that it will survive if implanted whilst the normal cell will die; that the difference in the conduct of the cells is due to the fact that the cancer cell has become "endowed with the gift of life," which constitutes it an independent creature; that the cancer cell is, in short, a new genus of organism vastly removed, phylogenetically, from the complex creature in which it originates.

Practically all students of the cancer problem are agreed that the cancer cell is derived directly from the normal cell, and the great majority of them are satisfied that no parasitic micro-organism plays any essential part in bringing about the change. The explanation of the difference in behaviour, within the body, of the progeny of the cancer cell and the progeny of the normal cell is, at present, the central problem of malignant disease. That cancer cells will survive and that normal cells will not survive when implanted is a generalisation to which there are so many obvious exceptions that it is improbable that such a peculiarity is the actual "vital difference" between the two sorts of cell. The successful transplantation followed by orderly growth of cutaneous epithelium and certain other tissues, and the phenomenon of the implantation cyst, prove that normal cells may survive if transplanted. The constant distinction between normal and malignant cells does not appear to be one of structure, composition, or metabolic activity, but rather one of conduct with respect to environment. The progeny of normal epithelial cells will divide and progress only in a direction away from the connective tissues; the progeny of carcinomatous cells are indifferent as to the direction in which they multiply.

That epithelial tissues are normally restrained and directed in their growth by purely physico-chemical processes has not been proved, yet the anticipation that it will be so proved seems to have engendered in many minds the belief that such is actually the case. This premature conclusion has distracted our attention from the otherwise obvious fact that in every living cell we encounter the incomprehensible phenomena of life and instinct. All the phenomena of the cosmos are not comprised within the domains of the physical sciences.

In my essay on Light, Pigmentation, and New Growth

(July, 1909) I postulated the existence in every normal cell capable of reproducing itself by fission of a psychic element akin to instinct. I opined that it is this element which controls and directs the behaviour of the cell in accordance with the particular "traditions" of its genus; and I gave reasons for my suggestion that the abnormal conduct of cancer cells with respect to their environment is due to an impairment or loss of this psychic principle. It certainly seems more probable that malignant disease is due to the loss of some controlling influence rather than to the accession of a quality novel and little short of supernatural in its character. I say little short of supernatural because it is against the order of nature that a new genus of unicellular animals should be repeatedly springing into existence and that the same genus should on every occasion be entirely exterminated. I am, Sir, yours faithfully,

WILFRED WATKINS-PITCHFORD, M.D. Lond., F.R.C.S. Eng.

The Government Laboratory, Johannesburg, Dec. 24th, 1911.

A PRESCRIPTION FOR COLITIS.

To the Editor of THE LANCET.

SIR,—Although I am not now in practice perhaps you will permit me to offer the profession through your courtesy a piece of therapeutic information that I have gained.

Many years ago I had a patient whom I generally attended on a midnight summons, suffering from abdominal pain, vomiting, and constipation. There was a history of diffuse peritonitis in childhood, and my diagnosis was a peritoneal adhesion which became inflamed by diet, chill, &c. I sent him to a distinguished surgeon, who said that he undoubtedly had appendicitis, and proposed an operation. This, however, the patient would not submit to.

In this case, of course, careful attention had to be bestowed upon the action of the bowels, and I tried many laxatives with more or less success. It finally struck me that a local emollient would be an excellent treatment and I wrote the following prescription:—

℞ P. gum. acaciæ ℥iv.
Syr. cascaræ sag. ℥ii.
Terrol. ℥ii.
Ft. pasta. ℥ii.

This kept my friend for ten years perfectly comfortable; he ceased taking it about one year ago as he does not now require any treatment. It was known as "Falkiner's table varnish" among our inner circle.

The other day I saw an old patient and friend of mine who is the widow of a distinguished London surgeon whom I conceived to be suffering from colitis, and sent the prescription to her, and being a great sufferer myself from the latter complaint when asking the chemist to send the copy of the prescription ordered a bottle for myself. I have only been using it for three days, but I have almost complete ease from the wearying sensation of colitis, which is so exhausting physically and mentally, and I also find that the hydrocarbon acts as a powerful intestinal disinfectant and deodoriser, and that it reduces the production of gases. Trusting that my experience may be of utility and enable many of my professional brothers to give relief in troublesome cases,

I am, Sir, yours faithfully,

Dublin, Jan. 10th, 1912. NINIAN M. FALKINER.

THE ACTION OF RADIUM ON MALIGNANT GROWTHS.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a letter which appeared in THE LANCET of Jan. 6th under the above title by Dr. F. L. de Verteuil, Surgeon, R.N. (retired), who, in referring to the different theories that have been advanced on the essential therapeutics of such radio-active agencies as radium and the X rays, ascribes priority in regard to one of them to Mr. Deane Butcher—namely, that of the induction of auto-vaccination by the X rays, as revealed by a series of independent estimations of the opsonic index against the particular pathogenic micro-organism concerned in those infectious maladies in which the lymphatic glands become involved. As Dr. de Verteuil is, in this respect, under a slight misapprehension, I beg leave to refer him to a contribution made by me to THE LANCET in 1907 (Vol. I., p. 215), as well as to the *Archives of the Roentgen Ray* for June, 1910, p. 2, where Mr. Deane Butcher urges a plea for the pressing requirement of a continuance and repetition of the line of research previously adopted by me.

I find that, up to date, my observations and experiments in the afebrile types of tuberculosis have been repeated independently by Dr. Lawrence and Dr. Crane, of the United States, both of whom corroborated and confirmed them. Also by Messrs. Paoli and Nuncioni, of Italy, who applied the X rays to the lymphatic glands involved in primary syphilis, confirming my views. In this country this fascinating research has been neglected, partly because radiologists or radiographers are more concerned with the electro-mechanics of apparatus construction, and the getting of mere results, than they are with pathology or clinical medicine. The loose and unscientific use of the term "vaccination" in the above reference is, in my opinion, calculated to give offence to the intelligence of both pathologists and clinicians.

Surely the term "vaccination," in its modern acceptation, connotes the introduction into the human organism of a certain number of killed and sterilised pathogenic micro-organisms, which specifically pertain to a particular malady, for the purpose of producing an increased resisting power against that particular micro-organism by evoking one or more precise physiological reactions in place of the pathological reactions, manifestations of which exist at the site of the lesion and in the system. By the term "auto-vaccination" it was intended to connote the further development or completion of the physiological process, consequent upon an infection, in conformity with the protective mechanisms of the organism, it being recognised that a pathological manifestation resulted from an incoördination in the chain of processes taking place during a reaction.

To speak of the X rays causing a "vaccination" or of "producing antitoxins" by stimulating leucocytes, can never appeal to the pathologist, and at the meeting of the annual congress of the British Medical Association held at the Imperial Institute, 1910, I felt obliged to make a gentle protest in this reference. On that occasion an instructive paper was read by Dr. W. S. Lazarus-Barlow, entitled "Radiation and Biological Processes; with Some Reference to the Skotographic Action of Animal Tissue." Dr. Lazarus-Barlow is, above all other things, a pathologist, and his observations are highly interesting as regards those minute finer changes in protoplasm which are more of a molecular nature than of a mere chemical change. I would recommend this paper and its study to Dr. de Verteuil, who seems to be attracted by the tertiary grosser changes of the tissues. These finer changes are far beyond the power of any microscope to reveal. I am, Sir, yours faithfully,

Wimpole-street, W., Jan. 9th, 1912. H. D. MCCULLOCH.

LOCAL REACTION IN TUBERCULIN TREATMENT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 30th, 1911, Dr. E. E. Prest contributes a letter on Some Points in the Treatment of Pulmonary Tuberculosis. Dr. Prest states he noticed "that cases in which there is a well-marked local reaction to an injection of tuberculin have relatively a favourable prognosis."

With reference to this statement, it is noteworthy that as long ago as 1897 Dr. Carl Spengler, of Davos, emphasised the high importance of local reactions in the administration of tuberculin. He showed that the bactericidal action, indirectly induced by tuberculin, varies with the intensity of the local reactions. Further, from his extensive researches he pointed out that the intensity of the local reaction at the seat of injection corresponds with the intensity of the local reaction at the foci of disease. (See Carl Spengler's article, "Über Tuberkulinbehandlung," published in 1897 by F. Schuler, Chur.) Obviously, the intensity of the local reactions must be carefully regulated.

When Carl Spengler in 1904 introduced the use of tuberculin derived from bovine tubercle bacilli, the importance of local reactions became even more evident. Without attention to these the wrong kind of tuberculin must often be used. Of course many cases are unsuitable for tuberculin

treatment, but those that are suitable should be treated correctly.

Although it is true that Dr. Spengler now uses his "Immune Substances (I.K) Treatment" in preference to tuberculin, because, in his opinion, the treatment when used correctly gives better results than tuberculin treatment, yet in these days, when tuberculin is so much discussed, it seems important that Spengler's work on the subject should be carefully studied.—I am, Sir, yours faithfully,

H. WM. GODFREY, M.B. Aberd.

Frinton-on-Sea, Jan. 16th, 1912.

THE MEETING OF THE CANADIAN PUBLIC HEALTH ASSOCIATION IN MONTREAL.

(FROM OUR SPECIAL CORRESPONDENT.)

(Concluded from p. 126.)

PERHAPS the most important, as well as the most genuinely interesting, of all the meetings was that of the second general session, when a symposium on Town-planning and Housing was held.

Town Planning and Housing.

Dr. CHAS. A. HODGETTS (Ottawa), medical adviser to the Commission on Conservation, read the first paper, which dealt with town-planning and housing. Dr. Hodgetts was by no means complimentary to the manner in which most of the towns of Canada are planned or built. He said that the lumber town of 40 years ago was still a lumber town. It had not risen to a realisation of its importance or to the dignity of its position as the Federal capital of a great and growing nation. He also adversely criticised the planning and housing facilities of Montreal.

Dr. J. E. LABERGE, assistant city medical health officer of Montreal, discussed the matter from the hygienic standpoint.

Dr. CHAS. J. C. O. HASTINGS, medical officer of health of Toronto, read a paper on housing problems in which he described the insanitary conditions existing in the slum districts of New York, Milwaukee, and Toronto. He pointed out that Toronto had its slums, and it was of no avail to attempt to disguise the fact. They must wake up, as other cities were waking up, to prevailing conditions and not live in a "fool's paradise." In Toronto, he said, there were 919 families living under distinctly insanitary conditions, some only in one-room tenements or in cellars. Tenement houses he declared to be nothing more or less than mere human "packing houses," and he concluded by urging the securing of transport facilities to districts on the outside of cities, where people could be properly housed in individual homes in beautiful garden cities.

Mr. W. D. LIGHTALL, K.C., spoke on the subject of Re-housing in Canada, and severely censured the apathetic attitude of municipalities and citizens towards the disgraceful conditions with regard to housing that prevail in many cities of Canada.

Ventilation of Private Houses.

In the Section of Sanitary Engineers and Architects among several papers of interest read was one by Mr. T. W. LUDLOW, Professor of Architecture, McGill University, on Natural Ventilation Applied to Private Houses. Professor Ludlow said that it was no unusual thing in Montreal and elsewhere in Canada to find the houses sealed against all possible ventilation by double windows screwed tightly to the inner sash. The so-called ventilating devices were worse than useless, especially when they were carefully covered over with strips of paper. Since the advent of the radiator-heating system ventilation had become a negligible quantity in dwellings owing to the absence of the old-fashioned open fire-place with a chimney for each room.

Conditions in Canadian Cities.

In the same section Mr. RAWSON GARDNER, President of the Architects' Association of Montreal, discussed conditions existing or arising in Canadian cities. Mr. Gardner said that the invasion of Canada by such a multitude of foreigners tended to create congestion and slums, a tendency that was augmented by the cold winters experienced in Canada. But light and air were a *sine quâ non* for each individual. He suggested that houses should be built around four sides of a block, with an inner courtyard for a playground and for flowers. He also thought that there should be a beautiful driveway extending along the bank of the St. Lawrence, from the rapids to the Victoria Bridge, connecting with the proposed boulevard along the aqueduct, and this in turn should be linked with the Mount Royal Park Boulevard. There was no necessity for any shack town on the edges of the city, and he looked forward to the establishment of garden cities about Montreal similar to those in England and Germany.

Biological Sewage Disposal.

The last general session of the meeting was the most instructive from a scientific standpoint, being devoted to a symposium on Biological Sewage Disposal.

Dr. P. H. BRYCE (Ottawa), chief medical officer of the Department of the Interior, dealt with the physical and economic aspects of biological sewage disposal.

Mr. T. AIRD MURRAY (Toronto), in treating of the engineering problems involved in biological methods of sewage disposal, described the mode of sewage disposal designed by himself at Lethbridge in order to secure the maximum removal of suspended solids, and said that the most that had been done was to secure an effluent that could easily and economically be rendered non-pathogenic.

Dr. J. A. AMYOT, Professor of Hygiene at Toronto University, discussed the bacterial problems involved in biological methods of sewage disposal. He said that two methods were ordinarily employed for this purpose, the anaerobic and the oxidation, of which the oxidation method was by far more satisfactory, but even with it it was utterly impossible to secure any system in the results. The engineer must decide the exact way in which the system should be worked. Dr. Amyot said that slow sand filtration was not enough to depend on. Disinfection also must be employed.

Dr. G. G. NASMYTH (Toronto) read a paper on the Chemical Principles of Sewage Disposal Methods. He said he believed that the trickling filter system from the point of view of economy and success had come to stay, as this system was in line with the methods of nature.

Election of Officers.—Success of the Meeting.

The new officers elected are as follows: President, Dr. C. A. Hodgetts (Ottawa); Vice-Presidents, Dr. M. M. Seymour (Regina, Saskatchewan), Dr. J. W. S. McCullough (Toronto), Dr. E. Bayard Fisher (Fredericton); general secretary, Major Lorne Drum (Ottawa); treasurer, Dr. G. D. Porter (Toronto). As before, the Executive Council is composed of eminent health officers from every part of the Dominion. The next place of meeting will be Toronto.

The Public Health Association has begun in most favourable circumstances and its future success seems to be assured. From scientific, practical, and social view-points this meeting was successful in a high degree, largely owing to the forethought and energy displayed by its late President, Dr. Starkey, and by the general secretary, Major Lorne Drum, and to the fact that His Royal Highness the Governor-General took such a keen interest in the proceedings from beginning to end. As an example of the concern for the success of the meeting, His Royal Highness on the morning of Dec. 14th paid an informal visit to the medical building of the McGill University, in which the meetings of the sections were held, by the courtesy of the Dean and Faculty of the University, and visited all the sections. It may also be said that membership of the Canadian Public Health Association is not confined to medical men: members of the laity are welcomed, as it is recognised that for such an association to do efficient work it must have the intelligent coöperation of the community at large.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN (UNIVERSITY OF LONDON).—The council has appointed Dr. Frederick Ransom internal examiner in pharmacology for the University of Cambridge, late assistant to Professor Behring and Professor Hans Meyer, to be lecturer and head of the Department of Pharmacology.—The examination for entrance scholarships will be held on May 28th and two days following. Forms of entrance and all particulars can be obtained on application to the secretary and warden.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Appeal of the Royal Infirmary against Assessment of its Glanydon Premises.

THE board of management of the Royal Infirmary has appealed against the assessment by the Conway Union regarding Glanydon Convalescent House. The case was heard at the Denbighshire Quarter Sessions at Ruthin and judgment was delivered on Jan. 6th. There were two lots of premises concerned in the appeal—those of Old Glanydon and those of New Glanydon. As regards Old Glanydon, these were originally assessed at £230 gross and £184 net, but these figures were afterwards reduced by the assessment committee to £200 and £160. On this part of their case the appellants failed. In the case of New Glanydon, there was, said the chairman, an important principle in question. The respondents contended that the cost of construction must be the measure by which the amount of assessment should be arrived at. The court was unable to adopt that view. It was quite impossible to apply the principle universally. There had been extra cost in order not to destroy the amenities of the locality. In other cases considerable expenditure had been incurred in buildings of this kind in order to conform with local by-laws. The appellants' case was that the original cost of construction must be entirely left out and that the court was only concerned with what rent a hypothetical tenant would be willing to pay for the premises. The court, again, could not adopt that view. They took, however, the original cost of the premises as a starting point, and with the other evidence to guide them endeavoured to arrive at a fair and reasonable assessment. The appellants succeeded and the assessment was reduced from £800 gross to £545, and from £640 net to £436. The court also decided that the respondents must pay the appellents' costs in the appeal, excluding such costs as related solely to Old Glanydon.

The Need for School Clinics.

Attempts are being made around Manchester to arouse interest in the question of the need for school clinics. At a meeting of the Women's Labour League recently held in Middleton a resolution was passed calling upon the Government to set aside a grant of £1,000,000 for the establishment of school clinics.

Charitable Bequests amounting to £26,000.

The late Mr. James Wilcock, of Blackburn, the chairman of the Refuge Assurance Committee, who died a few days ago, left £26,050 to charities as follows: Endowment fund of Blackburn branch of the new Charity Organisation Society, £5000; Imperial Cancer Research Fund (to which he gave £1000 in his lifetime), £4000; Blackburn and East Lancashire Infirmary, £2000; Blackburn Orphanage, £2000; Edgworth Home for Children, £2000; Blackburn and District Nursing Association, £2000; Müller's Orphanage, Bristol, £2000; Blackburn Ragged School, £1000; and lesser sums to a large number of other deserving charities.

Workmen's Compensation: Dependency of Fathers and Brothers: Important Case.

Judge Mellor, K.C., in the Manchester county court on Jan. 12th, gave an important decision on a somewhat novel case under the Workmen's Compensation Act. A painter, resident at Withington, while working on a ladder was thrown to the ground through the ladder slipping. His skull was fractured and he died immediately. Under this Act his father, mother, and five brothers and sisters all sought compensation from the employer on the ground that they had been partially dependent upon the earnings of the deceased. Of the 3 guineas that constituted the total income of the family per week, the deceased contributed regularly £1. It was contended that as the father was 54 years of age, and could not get work so readily, the family was really more dependent on the deceased than upon the father. It appears that a decision given by the Scottish courts held that those members of a family who were not working must be regarded as dependent on those who did earn wages, and it was therefore contended that in this case the father and some of the children were not legally entitled to compensation. The judge said that the question of total or partial dependency was a matter of fact and not of law. Each case had to be decided entirely on its own merits. He found that there was partial dependency in the case of each claimant, and assessed the compensation at £80, with costs on the higher (B) scale.

Prosecution under the Post Office Act: Improper Circulars.

An important prosecution under the Post Office Act was brought before the Manchester city stipendiary on Jan. 11th, when a young married couple who lived at Bugsworth, Derbyshire, were charged with sending an indecent print through the post on Dec. 21st. Mr. Pearce, who prosecuted on behalf of the Public Prosecutor, said it was alleged that the accused had sent through the post a circular relating to a certain article. The circular he handed to the bench. It was not alleged by the prosecution that there was anything indecent in regard to the mere selling of the article; the prosecution was taken because the circular, which was sent out broadcast, was in its terms improper. The method of conducting the business was an undesirable one. It was alleged that to get in touch with the persons to whom the articles were to be submitted the accused searched for announcements of engagements, and in addition for announcements of births. The allegation was that they sent to the two persons named in the announcements either a letter or one of the circulars produced. For the defence it was not denied that the communications had been sent through the post by the defendants, but it was contended that the circular was not improper. The stipendiary magistrate imposed a fine of £20 and 10 guineas costs on the male defendant, and £10 without costs on the female defendant, and in doing so he said the public ought to be protected from having their breakfast tables contaminated in the way described. He was satisfied that the defendants had been sending out the circulars, uninvited, to unmarried men and women. He had no power to send defendants to prison, though he was not at all sure that prison was not the proper penalty for an offence of that kind.

Jan. 16th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday in Liverpool.

ON Sunday, Jan. 14th, the collections in the various places of worship on behalf of the Hospital Sunday Fund took place. The weather, as in the past few years, was most unpropitious, wet and fog prevailing. The result was very disappointing, nearly all the collections showing a marked decrease. The Ullet-road Unitarian Church heads the list with a total of £575, as against £687 last year. Sefton Park Presbyterian Church comes second with £358, compared with £528 last year. Decreases all round were unfortunately experienced. The problem which confronts the Hospital Sunday Committee arises from the fact that, whilst the requirements of the hospitals are ever increasing, the annual church collections appear to be gradually shrinking. At all events, this has been the case during the last four years. This year an innovation has been made in the mode of collection. Some 6000 small "Red Cross envelopes" have been issued to facilitate the receipt of contributions from those who were sick or who for other reasons were unable to attend the churches on the day of collection. The result of this new arrangement may improve matters somewhat; at least, the committee has hopes of an improvement later, when the envelopes are returned.

Death of Mr. James Taylor, F.R.C.S.

The death occurred of Mr. James Taylor, of Chester, on Jan. 14th, at the age of 72 years. The deceased was highly esteemed in Chester, where he had been in practice since the "seventies." He was formerly honorary surgeon to the Chester General Infirmary, and held many honorary offices in connexion with his profession. He was an ex-President of the Lancashire and Cheshire Branch of the British Medical Association, and also held honorary offices in connexion with the North of England Obstetrical and Gynæcological Society. He obtained the Fellowship of the Royal College of Surgeons of England in 1882. He was also a justice of the peace for the city of Chester, of which he was a prominent citizen. The funeral took place on

Wednesday at Chester Cemetery, the first part of the service being held at St. John's Church. It was characteristic of his thought for others that on the morning of the day of his death he expressed the wish that if the day of his funeral should be cold or wet any friends who stood round the grave-side should be told to keep their hats on.

Jan. 16th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University Colston Society, Bristol.

THE thirteenth annual dinner, presided over by Sir Isambard Owen, Vice-Chancellor, took place on Jan. 15th in the large hall of the University. The chairman, in proposing "The Pious Memory of Edward Colston," said that the support of research, a task which the society has lately adopted as its chief *raison d'être*, would have commended itself highly to Colston, for research was the very life of a modern university. He said that if the relative narrowness of the available funds were considered, the output of research in Britain was very satisfactory, and the amount of original work being done in Bristol equally so. The treasurer announced that the amount collected during the year was £450. The toast of "The Guest," proposed by Mr. Cyril Norwood, headmaster of Bristol Grammar School, called forth a most interesting speech in reply from Sir A. T. Quiller-Couch. He said he would consider only that side of the University life on which he could speak with knowledge—the romantic side. The University had its charter; let it add one syllable to this, and acquire a character—something to mark off Bristol by itself among the nations. To achieve this a wide outlook was necessary. They must be in line with the general culture of Europe. The formation of hostels, where students might meet to discuss beliefs and disbeliefs, would encourage this diffusion of thought. He said that Bristol had one great asset as a seat of learning—its spirit of romance. He spoke of Bristol as the most romantic city in England, next to Oxford and, perhaps, Cambridge. But antiquity was not the whole secret. They must attract youth, and encourage the free and joyful spirit of youth. Professor Lloyd Morgan, who followed with the toast of "The City of Bristol," made an interesting allusion to the neighbouring Druidical circle at Stanton Drew as a proof that Bristol was a very ancient seat of learning. Mr. Palliser Martin, president of the Chamber of Commerce, pleaded for the establishment of a faculty of commerce; and the Right Hon. Henry Hobhouse, Pro-Chancellor, spoke of the urgent need of encouragement for research in agriculture, such as Bristol University has undertaken, quoting from a letter by Sir William Ramsay in support of his plea. Mr. Hobhouse made the important statement that the Board of Agriculture had undertaken to provide the University with a capital sum of £5000 and an annual income of £3500 to build and endow a department of agriculture, provided a capital sum of £5000 was raised locally. The new president, Mr. Henry H. Wills, was introduced to the chair, and the proceedings came to an end.

Bristol Dispensary.

At the annual meeting of the Bristol Dispensary held recently at the central premises of the institution, an increase of work was recorded, the total number of new patients during 1911 being 13,086, an advance of 1412 on 1910. The midwifery notes, of which 728 were used, also showed an increase of 40 over the preceding year. Medical aid had been necessary in 40 confinement cases. The number of subscribers was larger by a considerable margin than in previous years, and this, together with an increase in the sale of notes and several substantial legacies and donations, has placed the dispensary in a satisfactory financial position. Mr. Fenwick Richards, the chairman, in commenting on the secretary's report, said that some falling off in the subscription list would be almost inevitable in 1912, owing to the introduction of the Insurance Act.

Bristol Medical Charities.

During 1911 the employees of Messrs. J. S. Fry and Sons collected £703 for the various medical charities of Bristol. The employees of Messrs. W. D. and H. O. Wills's branch of the Imperial Tobacco Company, Limited, at Bedminster, during 1911 collected £785 for the Bristol medical charities.

Sanitary Inspectors' Association.

A meeting of the South-Western branch of the Sanitary Inspectors' Association was held at the Guildhall, Bristol, on Jan. 13th. There was a good attendance. Mr. T. J. Crofts read a paper on Public Administration and its Problems. Mr. G. H. Gibson, in a paper on Housing and Overcrowding in the Smaller Districts, stated that the evils of overcrowding are as acute and far-reaching in smaller districts as they are in the slums of the great cities.

The Proposed Memorial Hospital to the late Sir Charles Dilke.

A meeting was recently held at Cinderford in connexion with the proposed memorial hospital to the late Sir Charles Dilke, and a subcommittee was appointed to prepare a practical scheme. Since then an admirer of the deceased baronet, who is anxious that the original proposal of a hospital should be carried out, has offered to defray half the cost of the erection of such an institution provided that the other half is raised by subscription. This practically settles the form that the memorial should take. About £1500 have been already subscribed, and as there has long been a desire locally for the provision of a general hospital in the Forest of Dean, there is no doubt but that the necessary sum will soon be obtained.

Refusal to Form an Insurance Panel.

At a meeting held under the auspices of the South-Western Branch of the British Medical Association at Exeter on Jan. 11th, attended by nearly 100 members of the medical profession practising in Devon and Cornwall, it was unanimously resolved to refuse to form a panel under the Insurance Act unless the six cardinal points are guaranteed by the Insurance Commissioners.

Proposed Crèche for Plymouth.

At a meeting convened last week by the Mayor and Mayoress of Plymouth it was decided to formulate a scheme for the installation of a day-nursery where poor mothers could leave their children when they went out to work. A provisional committee was appointed, and about £200 were contributed for the object.

The Question of Free Medical Treatment of School Children.

At the last meeting of the Salisbury Education Committee it was suggested that a "full-time" medical officer should be employed to treat the school children at the public expense. The vice-chairman, in reply, stated that in Salisbury there had been formed "care committees," and when a child was reported by the school medical officer to be in bad health steps were taken to impress on the parents the desirability of providing medical treatment. The results obtained had been most satisfactory, and the proposed appointment was unnecessary. The vice-chairman added that neither the Wilts County Committee nor the Salisbury Education Committee had as yet decided to provide free treatment for ailments reported upon in the course of medical inspection.

Whole-time Medical Appointments.

At a meeting of the St. Austell (Cornwall) board of guardians, held on Jan. 12th, much discussion took place over the recommendation from the general purposes committee and the district council that a whole-time medical officer should be appointed to perform the duties of medical officer to the workhouse and scattered homes, medical officer for the seventh district, and medical officer of health for the St. Austell urban and rural districts. The proposed appointment was to be for three years, at a salary of £400 per annum, exclusive of travelling expenses and drugs. Eventually it was decided to adjourn the question. The clerk stated that the Local Government Board was in favour of the appointment of a medical officer of health who was not engaged in private practice.

Death of Mr. Francis William Stowe Wicksteed, M.R.C.S. Eng., L.S.A.

Mr. Francis W. S. Wicksteed died at 3, Royal-terrace, Weston-super-Mare, on Jan. 8th, in his 71st year, from pneumonia, after a short illness. Mr. Wicksteed was the son of the late Mr. Henry Wicksteed, of Maidstone, and received his medical education at St. Bartholomew's Hospital, London, qualifying as M.R.C.S. Eng. and L.S.A. in 1863.

He went to Weston-super-Mare and was for some time in partnership with the late Dr. E. Martin. He had an extensive practice there and was extremely popular, being always a generous supporter of any movement for improvement. He was the first to promote a fine art exhibition in the town. Mr. Wicksteed was formerly consulting surgeon to the local hospital and was at one time the representative of the ratepayers on the old board of town commissioners. He was also an ardent Freemason and a large subscriber to Masonic charities. A good sportsman, he was in his earlier days a follower of the foxhounds. He was one of the first officers of the Royal Naval Reserve to be accepted for service at the front during the Boer war, but a serious attack of pneumonia prevented him from going to South Africa. Mr. Wicksteed retired from practice about 17 years ago and went to live in London, but he never lost interest in Weston-super-Mare, and visited the town frequently. Only a few days before his death he was at the banquet marking the installation of Dr. H. S. Ballance as Worshipful Master of St. Kew Lodge of Freemasons. Much sympathy is felt at Weston-super-Mare for his widow and five children. The funeral took place at Weston-super-Mare on Jan. 12th, the majority of the local members of the medical profession being present.

Jan. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Act: the Scottish Central Committee.

IT is hoped that there will soon be a conference between representatives of the medical corporations, representatives of the Universities, and representatives of the Scottish Committee of the British Medical Association, the object being that some common line of policy for the medical profession may be recommended for adoption. I understand that the conference may take place on Saturday next, and that its general object will be, as already stated in these columns, to form a Central Committee to deal with the Act in Scotland. For this purpose the Scottish Committee of the British Medical Association has been given autonomy.

Food Adulteration.

The annual report of the analytical chemist of the corporation of Glasgow has just been issued, and contains much that is interesting from the public point of view. Dealing with the Sale of Food and Drugs Act some commendable suggestions are made in the report. It is stated that owing to the new and ingenious methods of food manipulation that are constantly coming to light the task of the conscientious analyst is one of ever-increasing difficulty. In the United States, the British Colonies, and continental countries an authoritative opinion is soon obtainable as to new methods of food manipulation and the procedure to be followed, but this is not the case in Great Britain. During the *régime* of the present President of the Local Government Board a more enlightened policy was inaugurated, resulting in the publication of exhaustive and instructive reports, many of which suggested permissible limits for foreign matter in certain classes of foodstuffs. Unfortunately these recommendations were rendered ineffective because they lacked the official imprimatur either of the Government or the Local Government Board, and consequently in the law courts were regarded only as an expression of opinion. What is urgently needed, according to the report, is to establish a board of reference, thoroughly representative of the scientific and commercial interests involved, whose decisions should, after due notice, become law. This procedure was recommended by a Select Committee on Food Adulteration as far back as 1896, and has been endorsed and advocated time and again by all classes of the community interested in this important question. Apart altogether from the uniformity in procedure which would result from the establishment of such a board, an inestimable advantage would be the early notification of new forms of adulteration, which, under existing conditions, are often in operation a considerable time before their presence is even suspected by the analyst, much less detected.

Royal Samaritan Hospital for Women, Glasgow.

Last week new buildings in connexion with this hospital were opened by the Hon. Elsie Corbett, daughter of Lord Rowallan, chairman of the governing body. The new buildings consist of a heating and power adjunct and a laundry. Lord Rowallan, who presided, stated that the new buildings, which cost £5000, had been opened free of debt through the kindness of friends. The directors are asking for £10,000 for further necessary extension of the hospital, including a pathological laboratory.

Insanity Statistics in Glasgow.

According to the report of Mr. John Carswell, certifying physician in lunacy to Glasgow parish council, during the past year there were certified as insane in the city 330 males and 293 females. Only in the year 1907, when 332 males were certified, has this number of males been exceeded, while the number of females is the highest on record. Of the total, however, there were 179 who had previously been under certificate. This means that 444 were certified for the first time, and this gives the true estimate of the occurrence of insanity. This number is very slightly over the number for the past three years. The proportion per 100,000 of the population is 76 9, which is the highest recorded, though it has varied but slightly since 1907, when it was 73·6. Investigations into the question of age show that the occurrence of insanity between 15 and 45 is not increasing, whereas at ages over 45 it shows a tendency to increase.

Gray's Hospital, Elgin.

About a year ago Lord Mount Stephen promised a donation of £5000 to the Gray's Hospital, Elgin, on condition that a like sum was collected by the hospital trustees. Up to date £3434 19*s.* 8*d.* of this sum have been subscribed.

Medical Inspection of School Children in Banffshire.

At a meeting of the secondary education committee of the County of Banff, held in Banff on Jan. 15th, Dr. Alexander Grant was appointed medical inspector of school children for the county.

Aberdeen Royal Infirmary: Hospital Sunday Collections.

The annual church collections on behalf of the Aberdeen Royal Infirmary were made on Jan. 7th in most of the churches in Aberdeen. The total amount collected was over £820. The sum collected in the Established churches amounted to very nearly £400 and in the United Free churches to nearly £350. A few churches have not as yet sent in their returns and in several churches the collection was not taken. So far as results go, they appear to be very much on a level with those of last year.

Aberdeen Royal Infirmary and Asylum Managers.

A statutory joint meeting of the Aberdeen Royal Infirmary and Royal Asylum Boards was held on Jan. 12th. The clerk read a summary showing that in the course of the past year 27 life managers had died and 92 had been admitted. The roll for the current year consists of 32 managers (*ex-officiis*), 933 life managers, 36 nominees of congregations, 20 nominees of employees in public works, &c., 59 nominees of districts and parishes, 10 nominees of presbyteries, &c., 61 annual subscribers (exclusive of those who are life managers), making the total membership of the corporation 1151.

Death of the Matron of Aberdeen Royal Infirmary.

The death took place on Jan. 6th of Miss Grace Macnaughton, matron of the Aberdeen Royal Infirmary. Miss Macnaughton was born in Crieff and received her training as a nurse at the Edinburgh Royal Infirmary. For a time she acted as sister in the ward of Professor W. S. Greenfield. In April, 1898, she was appointed matron of the Aberdeen Royal Infirmary, and the duties of that office she faithfully discharged until within a short time of her death. The funeral took place on Jan. 10th.

Jan. 16th.

GUARDIANS AND DISTRICT MEDICAL OFFICERS.—The Horiton (Devon) board of guardians at a recent meeting discussed some alleged complaint against one of their district medical officers, when one of the members is reported to have said: "The board when appointing medical men should lay it down that they must attend urgent cases without an order, and without a patient being necessarily a pauper"

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Emigration.

THE emigrants who left Irish ports in 1911 were 1884 fewer in number than those of the preceding year, the numbers being 32,457 in 1910 and 30,573 in 1911.

The Women's National Health Association and the Insurance Act.

The latest development in connexion with the Insurance Act in Ireland has arisen from the action of the Women's National Health Association. It seems than on Jan. 6th, at an important meeting convened by the Women's National Health Association of Ireland and held at Ely House, Dublin, it was unanimously decided to form a section to be known as "The National Health Insurance Society," which should be competent to become an approved society under the Insurance Act. It was also decided to recommend all the branches of the association to organise meetings locally, to which delegates would be sent for the purpose of explaining the provisions of the Act. It was pointed out that this insurance section would carry on its operations quite apart from the ordinary work of the Women's National Health Association, and would have its own offices and agents. The honorary members of the branches would not have this work thrown on them, and they and the branch committees were asked only to help in organising preliminary meetings and circulating literature which contained correct information regarding the Act, and to obtain the insuranee of as many men and women as possible for the Women's National Health Association Insurance Section. By so doing the position and influence of the association would be greatly improved, and if the new section should obtain large funds by the adhesion of many thousands of members, it would be in a position to give contributions to the Women's National Health Association, in addition to giving extra benefits to its members. It was further pointed out that it would be to the advantage of the society to get as many strong and healthy people to join as possible. So far back as May, 1911, an advisory committee consisting of Sir J. B. Dougherty, Mr. T. W. Russell, M.P., Sir Henry Robinson, the Earl of Carrick, Sir John Lynch, Mr. W. M. Murphy, Mr. G. Dougherty, and Sir William J. Thompson, the Registrar-General for Ireland, was appointed at a council meeting of the Women's National Health Association to give counsel as to what course it should take with regard to its relations to the Insurance Bill, and this committee forwarded to the Women's National Health Association the following resolution which had been passed unanimously :—

That we recommend that the Women's National Health Association should take steps to form an approved society under the Act, provided that it is found, upon inquiry, through the various branches of the association, that a sufficient number of insured persons can be obtained to qualify as an independent society under Section 38, Subsection 1, of the Bill, as introduced into the House of Lords.

The subject was consequently brought before the annual meeting of the Clonmel branch of the Women's National Health Asscciation on Jan. 9th, when by 17 votes to 4 it was decided to leave the matter alone altogether, the feeling being that there were many benefit societies in Clonmel which the people might join if they liked, and that if the association launched into another undertaking it would drift away from what it was originally established for. At a meeting of the Belfast branch held on Jan. 13th a resolution was passed by a large majority not to take any action in relation to the Insurance Act, the branch being only a health organisation. On Jan. 12th, at Queenstown, the branch of the Women's National Health Association, by a considerable majority, decided to keep to their health work and not to touch the Insurance Act; while at the Cork branch, the matter was discussed, but was adjourned for further consideration.

The Belfast Medical Guild.

At a meeting held in the Medical Institute on Dec. 7th, 1911, it was decided to form an association, to be called "The Belfast Medical Guild," and a committee was appointed to draw up a constitution and submit the same for approval or amendment at the next general meeting. This has been now done, and a general meeting will be held in the Medical Institute, Belfast, on Wednesday next, Jan. 24th, to approve or to amend the draft of the constitution which has now been circulated amongst the medical practitioners of Belfast. The committee who have drawn up the constitution and by-laws of this new medical association have, they say in a covering letter to their medical brethren, been much impressed with the serious position in which general practitioners are now placed by the passing of the Insurance Act, and all feel that disastrous results can be averted only by a firm determination to combine and to stick loyally together to the end. It is only by such united action that they can have the slightest chance of fair play in the contest with the forces that seem now to be united against the members of the medical profession.

Typhoid Fever in Omagh.

There are at present 18 cases of typhoid fever in the Omagh fever hospital, seven having been admitted during the week ending Jan 13th.

Jan. 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Will of Professor Lannelongue.

Professor Lannelongue, whose death I notified a fortnight ago, in his will appoints M. Armand Fallières, President of the French Republic, his executor. The sum of 700,000 francs is left to the Institution for the Protection and Rehabilitation of Young Girls, in addition to the legacies already made, to come into operation after the death of Madame Lannelongue. To the local society of medical men of Gers an annuity of 1500 francs has been left for physicians in distress or for their widows. This disposition completes a donation, made by Professor Lannelongue during his life, to the General Association of French Medical Men, of which for many years he was President. To the University of Paris Professor Lannelongue leaves an annual sum of 500 francs to be used as the council shall decide. To the Faculty of Medicine of Paris he leaves a like annual sum of 500 francs for medical students in necessitous circumstances. To each of the "bureaux de bienfaisance" of Auch, Condom, and Castera-Verduzan, he leaves an annuity of 1200 francs. The commune of Castera-Verduzan benefits also by numerous legacies to assist the completion of the work undertaken by its mayor. The impetus given by Professor Lannelongue to the thermal springs of this locality is well known, springs that in the time of the Romans enjoyed considerable repute. All the professor's residuary fortune, after the payment of bequests, legacies, and charges, is to be devoted to the establishment in France of some important international or national work of a social or scientific character.

Treatment of the Oriental Boil (Bouton d'Orient) by Methylene Blue.

At the last meeting of the Society of Tropical Pathology M. Cardamatis and M. Melissidis recommended the use of methylene blue in Oriental boil in the following manner: Morning and evening a thick layer of methylene blue ointment is applied. This treatment is continued for from 15 to 20 or even (exceptionally) 30 days. At the outset of the treatment a slight irritation of the boil covered with the pomade is observed, as well as an increase in the amount of fluid secreted by the ulcerated surface. After 15 days of this treatment the boils are washed with soap-and-water and the patient is kept under observation for from 15 to 20 days further until the cure is complete. Only three cases have been thus treated so far, but according to the authors the results have been remarkable. The boils were cured completely and the resulting scars covered with sound skin. The first signs of cure were manifested about 10 days after the commencement of the treatment, and consisted in a diminution of the inflammatory zone surrounding each boil, subsidence of the swelling, and detachment of the scab from the periphery. After the shedding or accidental detachment of the scab a small superficial ulceration remains, secreting a serous liquid, which cicatrises speedily without the help of the methylene blue ointment. The scars are not

deep and are of a light rose colour, which distinguishes them from those resulting from other treatments.

Gift to the Paris Faculty of Medicine.

The council of the Faculty of Medicine has acknowledged and unanimously accepted a gift of 100,000 francs made to its dean. The donor is a medical man who has preserved the strictest anonymity. The proceeds of the 100,000 francs invested in the State Three per Cents. are to be expended in the best interests of the students of the Faculty of Medicine of the University of Paris. The distribution is to be made yearly, in a lump sum or divided, according to the candidature, among: students distinguished for their devotion to patients as shown by conduct in epidemics or on missions; students distinguished in medicine by discoveries, invention of clinical or laboratory methods, &c.; poor and deserving students, to whom exhibitions are to be given to defray the expense of curriculum, examinations, instruments, apparatus, journeys of scientific education in France or abroad, and so forth.

Reports on Public Health and the Hygiene of Dwellings.

On Jan. 9th the Academy of Medicine heard a communication from M. Mesureur, who is a candidate for the chair left vacant by the death of M. Henri Monod, late Director-General of Public Assistance. M. Mesureur discussed the public health reports and the hygiene of dwellings. He thinks that the insanitation of towns depends largely on that of the dwelling houses, and he adds that if the labouring class especially occupy unhealthy lodgings in so many cases it is because there are no others for them, as the population is increasing more rapidly than the building of dwellings. In 15 years the proportion, which in Paris was formerly one dwelling for 2·90 inhabitants, is now one for 4. According to M. Bertillon, out of 1,664,000 inhabitants of this class, 340,000 occupy dwellings actually infected. M. Mesureur proposes the demolition of all unhealthy dwellings and the development of building societies for workmen's dwellings. The Public Assistance has largely taken up these enterprises, which return an annual revenue of 3·25 per cent. M. Mesureur also proposes the establishment of a kind of sanitary council before which the tenants and the medical man should be called on to give their opinion.

The Rising of the Seine.

For some days the level of the Seine has again risen, and although there is no immediate reason for inquietude, nevertheless the recollection of the floods of two years ago gives rise to some apprehension as to the future. Already the Parisian boats are unable to continue their complete service, the banks of the Seine are covered with water, and in the suburbs the inhabitants have water in their cellars. In Paris itself many cellars are flooded, and some of the attendant evils are making themselves felt, for telephonic communication is difficult on certain lines on account of the flooding of the cellars of the Guttenberg Exchange. The swollen affluents of the Seine, it is feared, will for a few days yet continue to augment the river, but with fine weather the maximum may be reached without any serious consequences.

Jan. 16th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Crime and Suicide in the United States.

NEWSPAPER reports of crime in 23 States during a period of 30 days have been recently analysed and classified. The total population of these States was 51,179,015. In this population in one month 470 violent crimes had been committed, which is 1 in every 108,286, or approximately 9·5 to the million. Taking murders alone, the total of 245 gave in the population 1 in every 208,893, or approximately 4·8 to the million. On a yearly basis this would give 57·6 murders and 114 violent crimes to the million. In this consideration, however, cities like Chicago, Philadelphia, Cleveland, Cincinnati, Boston, and St. Louis were, as far as possible, left out. Mr. Andrew D. White set the murder-rate of the United States for 1910 at 126 to the million. According to the American *Spectator*, the combined suicide-rate of 100 American cities, which was 21·8 per 100,000 population in 1908 and 21 in 1909, fell to 19·7 in 1910. The rate for the City of New York was 18·9. San Francisco had the highest suicide-rate, the yearly average being 52 per 100,000 inhabitants for the period of 1900 to 1909. Suicide has been most frequent during the past 10 years in five cities of California and in Hoboken, N.J., which has a rate of 35 per 100,000.

Increase of Railroad Accidents.

The Public Service Commission has reported that for the month of October last there was a considerable increase in railroad accidents, but a decrease in the number of deaths and serious injuries as compared with the corresponding period of last year. The accidents numbered 5488, against 5302 in October, 1910, and 4447 in October, 1909. There were 19 persons killed and 139 seriously injured, while in 1910 27 were killed and 226 seriously injured.

New Surgeon-General of the Public Health and Marine Hospital Service.

Dr. Rupert Blue and Dr. J. H. White have been named as candidates for the Surgeon-Generalship of the United States Public Health and Marine Hospital Service, vacant by the death of Dr. Wyman. Dr. Blue, who is at present stationed in Hawaii, will be remembered for his great work in San Francisco during the campaign against plague there. Dr. White is at the present time in New Orleans, where he did excellent work a few years back in the yellow fever epidemic. It is said that the appointment has been offered to Dr. Blue.

The American Association for the Conservation of Vision.

This association is an organised and conscious movement complementary to the National Committee on the Prevention of Blindness in the United States, which has developed since the formation of the first definite effort by the appointment of the New York Association for the Blind on June 1st, 1908. Other States that have taken up the matter by the formation of commissions and societies for the prevention of blindness are Maryland, Ohio, Massachusetts, Kentucky, Pennsylvania, Wisconsin, and California. The Russell Sage Foundation created a committee and a national committee on the prevention of blindness to systematise and coördinate the efforts being made in various parts of the country to this end. But a new note was introduced into the work in respect of the many conditions causing impairment of eyesight without necessarily inducing blindness, of which defective illumination and certain industrial processes were the most common. The Association for the Conservation of Vision, which arose to meet these ends, endeavours to secure legislation for better standards of factory illumination, for better protection of the eyes of school children, and so forth. It has inaugurated a general campaign of public education through the magazine and newspaper press.

The New York Medical Journal.

The editorship in chief of the *New York Medical Journal*, vacant by the death of Dr. Frank P. Foster, has been filled by the appointment of Dr. C. E. de M. Sajous, of Philadelphia, as supervising editor, the remainder of the editorial staff remaining unchanged. Dr. Sajous has had a wide editorial experience, and his "Annual of the Universal Medical Sciences," later the "Cyclopædia of Practical Medicine," is well known. Dr. Sajous spent the six years from 1891 in original research work in Paris, of which the outcome was his recently published two volumes on the Internal Secretions and the Principles of Medicine. He will doubtless continue the honourable traditions so long and worthily sustained by the late Dr. Foster and maintain the *New York Medical Journal* in the first rank of American medical journalism.

Action by a Typhoid Carrier against the City of New York.

The cook known throughout America as "Typhoid Mary," it is said, is about to bring an action against the city of New York and the Health Department, claiming damages for being kept in confinement for three years. "Typhoid Mary" was first heard of in 1906, when six members of a household in which she was cook were stricken with typhoid fever. Careful investigations by Dr. Soper as to the cause of the outbreak showed that water and food were not responsible. Dr. Soper, finding that the family had changed cooks about three weeks before, investigated the antecedents of the cook, Mary Mallon. It was found that in almost every house in which she had

worked typhoid fever had broken out, and 26 cases of the disease were laid at her door, although Dr. Soper was able to trace only fragments of her history during ten years. The Health Department could not learn that the woman had ever had typhoid fever, and she was described as a robust, heavily built person. She declares that she never had typhoid fever, and objected strongly to being confined. On the complaint of the Health Department, however, she was incarcerated as a menace to the community, and was released only in February last on the plea of Dr. Lederle that she had been shut up long enough to learn the necessity for taking precautions. Mary Mallon now brings action on the ground that she was unjustly held prisoner, and that since her release she has been unable to follow her trade of cooking, and that her chances of making a living have been greatly reduced. This action gives rise to a very nice point of law: Can a person be properly imprisoned, or rather isolated, on the authority of the health officers on the ground that he is a menace to the community as a probable disseminator of disease? On the principle that the public welfare is the highest law this would appear to be sound practice; yet scarcely enough is known regarding the menace of a "disease-carrier" to make the case of Mary Mallon a desirable precedent. The whole matter will doubtless be thoroughly threshed out in the courts.

The Health Officer of the Port of New York.

As is known to readers of these letters, by a singular flaw in legislation, the health officer of this important port is a State appointed and not a Federal official, although the water highways of the nation are generally under central control. As the annual salary of the post is £2400 it has always been one of great interest to the political "bosses." Dr. Alvah H. Doty has been health officer for over 12 years, and has given universal satisfaction to the public and to his fellow practitioners, but that has not placated his political opponents. Dr. Doty's term expired on Feb. 28th last, and on May 30th following the Governor of the State appointed a commissioner to investigate the methods of the administration. This report has just been issued after an absurd investigation, in which ignorant immigrants were invited to testify concerning methods of treatment. A sample of their testimony was their protest against the "cruelty" of putting young babies out of doors in the coldest weather during their sleeping hours. A meeting was called at the Academy of Medicine on Dec. 13th last of the practitioners of New York to protest against this report, and several hundred attended. Resolutions of confidence in Dr. Doty were adopted and a petition to the Governor of New York State to maintain him in office was prepared. The Governor, however, has required Dr. Doty's resignation.

Rabies in New York City.

Interesting statistics have been compiled by the Department of Health, which show that the number of persons recommended for the Pasteur treatment after examination by the department was 182 in 1909, 262 in 1910, and 312 for the first eight months of 1911. There were more persons bitten than shown by these figures, since a large number call at the laboratory of their own volition whose cases are investigated but who are not advised to take the Pasteur treatment because the animals that bit them were not rabid. For the months of April, May, June, July, and August of 1911 the number of cases of this character was 236. The New York Pasteur Institute furnishes the information that for the year ending August 1st, 1910, there were 952 consultations for bites inflicted by dogs and cats, while the figures for the ensuing year were 1010. In 1910 377 such animals were examined and 152 positive cases of rabies were found. For the first seven months of the past year 349 animals were examined with 173 positive results. Of the total number of 2462 persons bitten 1743 were children.

War on Infantile Poliomyelitis.

As it is now believed by many observers that infantile paralysis is an infectious disease, communicated in the dust of the sick-room by an ultra-microscopic organism, the Department of Health has taken measures to combat its spread by the appointment of inspectors to all orthopædic hospitals and dispensaries to ensure complete reports of all cases presented. Cases will probably be isolated in the future, and other children in the family will be kept from school. Circulars will be issued giving a summary of our present knowledge of the disease and its treatment, and a minimum quarantine period of six weeks will be instituted. Bedding will be disinfected, and houses in which cases occur will be renovated or fumigated. Physicians will hence-forward be compelled to report all cases coming under the r notice.

Pensions for Nurses.

Mount Sinai Hospital has established a precedent in raising a fund of £12,000 for the use of nurses who have graduated from its training school and have subsequently supported themselves for at least 20 years by their profession. The fund will be administered by a committee of the Alumnæ Association, and it is understood that the latter will not be too strict in its rulings and may occasionally give relief where the full 20 years have not expired.

The City's Pure Food Policy.

The numerous cases of adulteration by retail dealers of common articles of food, as often reported in these letters, have drawn a statement from Health Commissioner Lederle to the effect that the municipal department, together with the State authorities, will never succeed in their efforts till they are empowered to supplement the work of the Federal officials. If this power is not conferred the Federal power will eventually become supreme. The city commissioner has ceased the mere confiscation of the adulterated food and has instituted criminal proceedings in all cases. This has struck fear into violators of the ordinances, who cannot suffer imprisonment without serious financial loss.

An Effort to Fight Insanity.

The State Charities Aid Association has recently issued a booklet, "Why Should Anyone Go Insane?" The sending out of this work is part of a campaign for the purpose of educating the public in the knowledge that insanity is preventable; 24,845 letters have been posted to clergymen, educators, teachers, and others, explaining the causes and prevention of insanity. There are 32,657 insane in the State hospitals, or 1 in every 20 of the adult population. It is hoped to develop the campaign along the lines so successfully followed in the fight against tuberculosis.

The Army Canteen.

Some years ago Congress abolished the army canteen under pressure from an immense number of amiable *a priori* thinkers who maintained that it was wrong for "Uncle Sam to be in the liquor business." A letter has been prepared by Dr. W. W. Keen, of Philadelphia, himself a total abstainer and non-smoker, and signed by 275 of the most prominent practitioners in the country, praying Congress to restore the soldiers' club. Nothing stronger than lager beer was ever sold at the canteen, together with tobacco and certain food delicacies. The profits were applied to the soldiers' mess. Since the abolition of the canteen drunkenness, desertions, and especially venereal disease, have been extremely prevalent and constitute a serious menace to the army. The canteen was immediately replaced by a circle of "dives" of the worst description, where adulterated whisky was sold to the men, who were then robbed by the diseased females who haunted these places. According to the report of Surgeon-Genera Torrey, the disease peril has come to outweigh in importance any other sanitary question which now confronts the army, and neither our national optimism nor the Anglo-Saxon disposition to ignore a subject which is offensive to the public can longer excuse us from facing the problem.

Dr. C. H. Mayo's Health.

Dr. Charles H. Mayo, one of the well-known Mayo brothers, whose surgical clinic at Rochester, Minnesota, has become a veritable Mecca for medical pilgrims of all nationalities, has had to undergo abdominal section twice within a week. On Dec. 15th last he was taken suddenly ill in New York with appendicitis and was operated on at the Presbyterian Hospital by Dr. Joseph A. Blake, a gangrenous appendix being removed. On the 22nd symptoms of acute cholecystitis set in, and he was again operated on and a number of gall-stones were removed. He has progressed favourably.

Jan. 6th.

THE NATIONAL INSURANCE ACT.

THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

A SPECIAL meeting of the Council of the British Medical Association was held at 429, Strand, London, on Wednesday afternoon, Jan. 17th. A largely signed requisition was before them from the members of the Association that an extraordinary general meeting of the whole constituency should be held to consider the position of the profession under the National Insurance Act. It is well known that the authorities of the Association consider that such an extraordinary general meeting of the whole body would be out of order on the particular proposition, but no definite statement as to the decision of the Council has been made public.

BRITISH MEDICAL ASSOCIATION REFORM COMMITTEE.

The Reform Committee, which came into being on Jan. 9th at the meeting of medical men in the Hammersmith Town-hall, has issued the following manifesto:—

To the Members of the Medical Profession in General and of the British Medical Association in Particular,—

The Provisional Executive of the British Medical Association Reform Committee, appointed by resolution at a public meeting of the profession held at the Hammersmith Town-hall on Tuesday, Jan. 9th, 1912, wishes to publish the following as an outline of its objects and policy.

1. This Committee exists solely for the purpose of enforcing the avowed policy of the British Medical Association in contra-distinction to the weakened version thereof expressed in the circular letter to Representatives under date Dec. 9th, 1911, which was signed by the chairman of Representative Meeting and chairman of Council, and will only continue to exist until the interests of the medical profession under the National Insurance Act, 1911, are adequately safeguarded without evasion, equivocation, or mental reservation of any kind.

2. The Committee is of opinion that the best method of obtaining this end is by the promotion of an Act of Parliament, through the British Medical Association, amending the National Insurance Act, 1911, in such a manner as will embody as a minimum the six-point programme of the British Medical Association. This opinion of the Committee is directly opposed to that of the existing Council of the British Medical Association—namely, that matters may now be left in the hands of the Commissioners to be dealt with in their regulations.

3. The Committee is of opinion that in its recent negotiations with the Government the existing Council of the Association has allowed itself to be too much influenced by political considerations, and by so doing have endangered the interests of the medical profession, and the Committee is further of opinion that the "ending or mending" of the present Council is the only method by which the confidence of the members of the British Medical Association in their official leaders can be restored.

4. In order to reform the existing Council the Committee suggests the enrolment in the Reform Committee of sufficient members in each division and branch as to ensure that a Representative be returned either to the Representative Body or to the Council who shall be in sympathy with, and will pledge himself to vote for, the policy laid down in the foregoing paragraphs. It also suggests the establishment of an Executive Committee in London composed of delegates of divisions to control the business and finances of the Reform Committee.

5. The Provisional Executive suggests that the Reform Committee should confer as soon as possible with all or any of the present medical organisations which have been formed for the purpose of dealing with the situation created by the Act, with a view to union.

6. The Committee is of opinion that every member of the profession should be a member of the British Medical Association, and urges every member of the Reform Committee to use their best endeavours to obtain new members and to persuade existing members to continue their membership.

The Reform Committee invites members of the British Medical Association who are in sympathy with the policy as set forth above to assist in the establishment of branches of the committee in their divisions and to lose no time in communicating with the Honorary Secretary, Provisional Executive Committee, at its offices, 29, Old Queen-street, Westminster, S.W. (Telephone, 1775 Victoria). The chairman is Dr. F. J. Smith, Mr. P. C. Raiment is honorary secretary, and Mr. Wilfrid Travers business manager.

TWO EXPOSITIONS OF THE ACT.

The National Insurance Act, 1911. Being a Treatise on the Scheme of National Health Insurance and Insurance against Unemployment created by that Act, with the Incorporated Enactments, full Explanatory Notes, Tables, and Examples. By ORME CLARKE, of the Inner Temple and Western Circuit, Barrister-at-law. With an Introduction by Sir JOHN SIMON, K.C.V.O., M.P., Solicitor-General. London, Sydney, and Calcutta: Butterworth and Co. 1912. Pp. 491. Price 12*s.* 6*d.*—Mr. Orme Clarke is very early in the field with an informing and lawyer-like commentary upon the National Insurance Act, and his book should before long be in the hands of everyone whose duties or inclinations impel him, we will not say to master so large and complex a subject, but to acquire accurate knowledge of those portions of the Act which immediately concern him. Mr. Clarke admits that the task of writing his treatise in the circumstances in which the Act was passed, and in view of the necessity for early publication, was no easy one, but we hope that, as he suggests, *olim meminisse juvabit.* No doubt when he has supplemented his recent labours by a similar exposition of the regulations now being pondered by the Commissioners he will be able to look back with satisfaction upon what he has accomplished—and decide whether a second edition should wait for the passing of an amending Act. Mr. Clarke acknowledges indebtedness for assistance to a legal colleague, Mr. Colin Smith, and has secured appreciation of his work by the Solicitor-General, who contributes a pregnant introductory note. The form of the book is that familiar to lawyers, and is also one convenient for laymen. An introduction is followed by the Act itself set out in full, with a full explanatory note, distinguished in the printing by a different type, following each section. The usual Tables of Cases and Statutes are inserted at the beginning, and material portions of the Interpretation Act, 1889, will be found at the end. Passing over the introductory summary, which is brief, but which makes tolerably clear the general scope of the Act in case this may have been forgotten, we naturally turn, in a work of this kind, to renew our acquaintance with those sections of the new statute which directly affect the medical profession, and none can do so without being struck at once by the meagreness of the information which they afford, and by the scanty consideration which Parliament was allowed to give to the case of the profession without whose coöperation the Act must remain unworkable. Section 15, which deals with medical benefits, manages to suggest a possible difficulty for which it provides no apparent solution. Insurance committees, as all are aware, are to adopt a system which will secure the right of the insured to select a medical practitioner from a panel to treat him, subject to the consent of the practitioner so selected. But what is to happen when a prospective patient is declined by a practitioner, and when he meets with a similar refusal from all the other members of the panel? According to the section, the system to be adopted must secure "the distribution amongst, and so far as practicable under arrangements made by, the several practitioners whose names are on the lists, of the insured persons who after due notice have failed to make any selection, or who have been refused by the practitioner whom they have selected." Mr. Clarke thus illustrates and speculates upon the situation. "A, B, and C are the practitioners on the list in a given area; D, an insured person in that area, has selected A as his practitioner, but A has refused to have him. Similarly, B and C refuse to have him, and A, B, and C are unable to arrange between themselves who is to take D. D would be one of the persons who would have to be distributed, and in the absence of arrangement between A, B, and C it is submitted that D's right to select would revive, and he would be allocated to A, who in fact had previously refused to have him. It is submitted that the exercise by a practitioner of his right to be placed on the list must carry with it the possibility of the abrogation of his right to refuse to treat any given

patient. *Sed quære* whether in such a case the practitioner is not entitled to persist in his refusal to treat the person in question. If so, *quære* whether the Commissioners may use their powers under the proviso and suspend the person's right to medical benefit?" We venture to question the soundness of Mr. Clarke's first two submissions, and lean rather to his latter two, but the case imagined has been left apparently not provided for, whether by design or owing to the manner in which the Act was passed, and it is one which adds weight to the arguments of those who insist upon a system of payment by fees for work done. The refusals to treat individual cases under a system of payment *per capita* would naturally be more numerous than under the other. However, "*quære*" and "*semble*" are words which the author finds himself frequently obliged to employ in his notes of explanation, and he raises under them a good many interesting questions for meditation and discussion. It may be mentioned that Sir John Simon, in his introduction, makes a very good point in favour of the inclusion of sickness and unemployment insurance in one Act. He says that as capacity to work is a condition without which unemployment benefit is not to be enjoyed, and as incapacity to work is equally a qualification necessary for those seeking sickness benefit, to have passed one half of the Act without the other would have meant either the claiming of unemployment benefit by those whose condition was due to physical incapacity, or the claiming of sick benefit by those in fact unemployed, according to which half of the Act had been allowed to take precedence of the other. The soundness of the argument is what might be expected from the able lawyer who puts it forward, although it must be recollected that Part II. of the Act only applies to certain groups of trades.

Everybody's Guide to the Insurance Act. By THOMAS SMITH, Barrister-at-Law, of the Inner Temple; Joint Author of "Points for Guardians and their Officers." London: Charles Knight and Co., Limited. Pp. 304. Price 1*s.* net.—The enormous number of persons directly affected by the Insurance Act renders the publication of a popular introduction to its provisions opportune, and Mr. Smith's work is, as its title implies, a guide of a popular nature rather than a legal text-book. In form it consists of a series of explanatory articles paraphrasing and commenting upon the Act, with references to the sections dealt with, the Act itself being printed in full without notes at the end of the book. In effect it is calculated to give a good general idea of the new law and of some of the difficulties likely to arise under it, and reference to, and comparison with, the text of the Act will generally show how far the author's version of its provisions is justified. Something more in the nature of a legal treatise will be required by those who desire to get as near to unimpeachable accuracy in their appreciation of details as the complexity of the subject will permit. It is not easy to paraphrase a section or sections of an Act of Parliament and to preserve at the same time their full meaning, especially if condensation is attempted at the same time. Mr. Smith sets out the following as one of three main principles upon which the Insurance Act is founded: "(1) It is founded on compulsion. So far as is possible, all employed persons who do not earn salaries or remuneration exceeding £160 a year are brought within the scheme." This may be correct as far as it goes, but the inclusion of employed persons earning more than £160 a year by manual labour is left to be gathered from the following page. Again, the case of persons refused by the medical practitioner whom they have selected is dealt with by saying "such persons will be distributed as far as possible amongst the medical practitioners on the list." Here "as far as possible" seems to be the author's version of "so far as practicable" in Section 15, Subsection 2 (A), words which there do not govern the distribution, but the making of arrangements for it by the several medical practitioners on the lists. Again, the words "the regulations may provide" occur at the commencement of what we take to be the author's version of Section 15, Subsection 4, which begins "the regulations shall provide." In dealing with the same section the author, we notice, characterises the provisions of Subsection 3 as "effecting a compromise which was apparently acceptable to the medical profession," a statement from which we should differ, even taking into consideration the qualifying adverb "apparently." Nevertheless, as a popular guide or as an introduction to a closer study of the Act Mr. Smith's work should be found useful.

INSURANCE COMMISSIONERS.

For the convenience of our readers we print the full lists of Insurance Commissioners officially appointed by the Treasury:—

English Insurance Commissioners.

Sir Robert L. Morant, K.C.B., chairman.
Mr. J. Smith Whitaker, deputy chairman.
Mr. John Swanwick Bradbury, C.B.
Mr. David James Shackleton.
Mr. James Lister Stead.
Mr. Thomas Neill.
Miss Mona Wilson.
The Chief Registrar of Friendly Societies.

Scottish Insurance Commissioners.

Mr. James Leishman, chairman.
Dr. John Christie McVail, LL.D., deputy chairman.
Mr. John M'Nicol.
Miss Mary Muirhead Paterson.
The Chief Registrar of Friendly Societies.

Irish Insurance Commissioners.

Mr. Joseph Aloysius Glynn, chairman.
Mr. Walter Samuel Kinnear, deputy chairman.
Dr. William Joseph Maguire.
Mrs. Marie Louise Dickie.
The Chief Registrar of Friendly Societies.

Welsh Insurance Commissioners.

Mr. Thomas John Hughes, chairman.
Dr. Harold Meredith Richards, deputy chairman.
Mr. John Rowland, M.V.O.
The Hon. Violet Douglas-Pennant.
The Chief Registrar of Friendly Societies.

Joint Committee.

The Lords Commissioners of the Treasury have also appointed a Joint Committee of the several bodies of Insurance Commissioners as follows:—

Mr. C. F. G. Masterman, M.P., chairman.
Sir Robert Morant, K.C.B., vice-chairman.
The chairmen for the time being of the several bodies of Commissioners *ex officio* members of Committee.
Mr. J. Smith Whitaker.
Mr. J. S. Bradbury, C.B., Chief Registrar of Friendly Societies.
Sir John Struthers, K.C.B.
Mrs. Louise Creighton.

The Joint Committee of Commissioners under the Act have appointed Mr. W. J. Braithwaite secretary and Mr. A. W. Watson chief actuary to the Joint Committee.

Obituary.

EDMUND DOWNES, M.D. BRUX., F.R.C.S. EDIN.

THE death is announced of Dr. Edmund Downes, which occurred at Eastbourne on Jan. 11th. He came of an old Northamptonshire family, and was born at Horton 68 years ago. After leaving school he entered upon a military career, obtaining a commission in the Royal Artillery and served for a few years. The study of medicine, however, had greater attractions for him, and in 1876 he took the M.D. degree at Brussels, and the L.R.C.P. diploma in London. He then offered himself to the Church Missionary Society, and was for some years engaged in the society's Kashmir Medical Mission. In 1882 at Calcutta he read a paper on the subject of the mission at the Decennial Missionary Conference. His health, however, broke down, and he was compelled to return to England. In 1884 he became a Fellow of the Royal College of Surgeons of Edinburgh, and in the same year settled at Eastbourne, where he soon had an extensive practice. While at the Sussex seaside town he centred his principal activities, apart from his profession, in the advancement of religious and philanthropic works. He was very fond of swimming and for 20 years was President of the Eastbourne Swimming Club. It was through ill-health that he retired from this position in December, 1909, and the

members presented him with an artistic illuminated address appreciative of his generous help. Of late years his health completely broke down, and his last serious illness extended over five months. In the early "eighties" Dr. Downes was a frequent contributor to THE LANCET, among his papers being, "Treatment of Acute Osteitis" in 1881; "Operation and Cure of Complete Congenital Occlusion of Os Uteri," in 1882; and "The Use of the Catgut Ligature," in 1883.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Julius Weil, of the Schlachtensee Sanatorium, aged 42.—Dr. Bernhard Schuchardt, for many years chief of the Medical Department of the Ducal Government of Gotha, aged 88. He was a voluminous writer on many subjects—hygiene, geographical pathology, the history of medicine, pharmacology, &c. His son, Karl August Schuchardt, was director of the Stettin Hospital, and had attained to considerable eminence as a surgeon before his death many years ago.—Dr. Kroemer, of Conradstein, Medical Privy Councillor.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology, held on Jan. 4th, 5th, 8th, and 9th, 94 candidates presented themselves, of whom 49 were approved and 45 were rejected. The following are the names of the successful candidates:—

Calcutta, Medical College, Calcutta; Narayan Krishna Bal, L.M.S. Bombay, Bombay University; Percy William Barnden, London Hospital; Zaki Mikhail Bishara, Cairo and London Hospital; Norman Briggs, Leeds University; Marcus Thomas Gonzalez Clegg, B.A. Cantab., Cambridge University; Subramanya Doraisamy, Madras University and Middlesex Hospital; Herman Gerald Dresing, Guy's Hospital; Charles Theodore James Drobig, St. Mary's Hospital; James Angel Durante, London Hospital; Ahmed Fahmi El-Hakim, Cairo and London Hospital; Frederick Ernest Feilden, Middlesex Hospital; Hassell Dyer Field, St. Thomas's Hospital; George Cowley Gell, Middlesex Hospital; Lionel Augustine Graham, Guy's Hospital; Alfred Risdon Hacker, Westminster Hospital and King's College; Arthur Herbert Harkness, Guy's Hospital; Frank Cecil Harrison, Sheffield University; Abdel Halim Hilmy, Cairo and St. Thomas's Hospital; Tom Jones, B.A. Cantab., Cambridge University; Charles George Gordon Keane, St. Mary's Hospital; Merlin Kingsley, L.M.S. Calcutta, Calcutta Medical College; Felix Edward Ricardo Laborda, Guy's Hospital; James Arthur Liley, London Hospital; Kambeeranda Cariapa Mandana, Madras University and Middlesex Hospital; Alwyne Harold Manfield, London Hospital; Bhamini Mohan Mitra, Calcutta Medical College and Middlesex Hospital; Newman Frederick Norman, Cambridge University and St. Bartholomew's Hospital; Guy William Parry, St. Bartholomew's Hospital; John Meredydd Parry, University College, Cardiff; Owen Guy Parry-Jones, B.A. Oxon., Guy's Hospital; William Linnell Partridge, Guy's Hospital; Haydu Peters, Middlesex Hospital; Gabriel Francis Rodrigues, Madras University and University College; Harold Arthur Rowell, St. Thomas's Hospital; Adrian St. Johnston, St. Thomas's Hospital; John Thomas Samuel, University College, Cardiff; Noel Humphrey Wykeham Saw, Guy's Hospital; Frederick Gilbert Laughton Scott, B.A. Oxon., Oxford University; William Goodman Shakespeare, King's College; Gerald Davenant Shann, St. George's Hospital and King's College; Edward Benjamin Sunderland, University College; Leonard Hankinson Terry, St. Bartholomew's Hospital; Richard Roland Htoon Oo Tha, University College; Myles Denison Boswell Tonks, London Hospital; Cedric Norman Vaisey, Bristol University; and John Rollo Noel Warburton, St. Thomas's Hospital.

At the quarterly examination in Practical Pharmacy, held on Jan. 11th, the following gentlemen were approved:—

George William Macbeath Andrew, Cambridge University and Guy's Hospital; Louis David Cohen, London Hospital; Alfred Beuthin Danby, Guy's Hospital; William Everard Sherard Digby, Guy's Hospital; George Eldridge Dyas, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; William Kelsey Fry, Guy's Hospital; Norman Grellier, L.D.S. Eng., Charing Cross Hospital; Harry James Hoby, New Zealand University and Guy's Hospital; James Evelyn Thoresby Jones, University College Hospital; Arthur Wellington Matthew, London Hospital; Edward Jocelyn Nangle, B.A. Cantab., Cambridge University and St. Mary's Hospital; Leonard Robert Pickett, Guy's Hospital; Arthur Starkie Plant, Manchester University; Frank Pearce Pocock, King's College and Westminster Hospital; Pierre Roux, London Hospital; Ahmad Hussein Samy, St. Bartholomew's Hospital; Alexander Stanger Seabrooke, B.A. Cantab., Cambridge University and Guy's Hospital; Percy Ward, Sheffield University; Clement Arthur Webster, Manchester University; Charles Alexander Weller, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; and Stanley Wickenden, Guy's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Uhthoff, of Breslau, has been appointed Professor of Ophthalmology, in succession to the late Dr. Michel. Dr. Oskar Huber, Director of the Medical Side of the Augusta Victoria Hospital in Schöneberg, has been granted the title of Professor. An Honorary Professorship has also been conferred on Dr. August von Wassermann, of the Institute of Infectious Diseases, who is so well known in connexion with blood tests.—*Breslau:* Dr. Uhtoff, who has accepted a chair of Ophthalmology in Berlin, has decided to remain in Breslau. Dr. Herman Coenen, Oberarzt of the University Surgical Clinic; and Dr. Alexander Bittorf, Oberarzt of the University Medical Clinic, have been granted the title of Professor.—*Brussels:* Professor Thiriar, the eminent surgeon, is retiring. His post as Director of the First Surgical Clinic has been conferred upon Professor A. Delpage, Dr. J. Verhoogen becoming Director of the Second Surgical Clinic.—*Freiburg:* Dr. Mangold, of Greifswald, has been recognised as *privat-docent* of Physiology.—*Göttingen:* Dr. Werner Rosenthal, *privat-docent* of Hygiene, has been granted the title of Professor; Dr. Eugen Muthmann has been recognised as *privat-docent* of Anatomy.—*Greifswald:* Dr. Martin Kochmann, *privat-docent* of Pharmacology, has been granted the title of Professor.—*Heidelberg:* Dr. Franz Lust has been appointed Oberarzt of the University Children's Clinic in succession to Dr. Tobler.—*Kharkoff:* Dr. Poliakoff, Professor at Dorpat (Iurieff), has been appointed to the chair of Histology.—*Kiel:* Dr. H. Schlecht has been recognised as *privat-docent* of Medicine.—*Königsberg:* The title of Professor has been granted to Dr. Isfried Hofbauer, *privat-docent* of Gynæcology; Dr. Max Draudt and Dr. Rudolf Haecker, Oberärzte of the Surgical Clinic; and Dr. Oskar Ehrhardt, *privat-docent* of Surgery.—*Leipsic:* Dr. Ewald Hering, professor of physiology, has been made a Knight of the Bavarian Maximilian Order.—*Lemberg:* Dr. Stanislas Opolski has been appointed Extraordinary Professor of Chemistry in the Medical Faculty.—*Magdeburg:* Dr. W. Thom, an eminent gynæcologist, has been granted the title of Professor.—*Modena:* Dr. Giovanni Quadri has been recognised as *privat-docent* of Medical Pathology.—*Strasburg:* Dr. Paul Asch, *privat-docent* of Urology, has been granted the title of Professor.—*Wiesbaden:* Dr. Peter Hackenbruch, an eminent surgeon, has been granted the title of Professor.—*Würzburg:* Dr. Ernst Magnus-Alsleben, who followed his chief, Professor D. Gerhardt, from Basle, has been recognised as *privat-docent* of Medicine.

LONGEVITY.—Mr. Edgar Jones, M.R.C.S., of Great Burstead, Essex, who has recently entered his 103rd year, was born at Bristol, and his brother, the late Alderman John Averay Jones, was a former mayor of that city.

OYSTERS AND ENTERIC FEVER.—At the last meeting of the Kingswood (Gloucestershire) urban council the medical officer of health, Mr. C. J. Perrott, reported that two cases of enteric fever, probably due to eating oysters, had been recently reported.

PRESENTATION TO A MEDICAL PRACTITIONER.—At a meeting of members of the Teignmouth (Devon) Corps of the St. John Ambulance Brigade, held on Jan. 11th, Mr. George Herbert Johnson, L.R.C.P., L.M.Edin., M.R.C.S. Eng., was presented with a silver smoker's table-lamp, suitably inscribed, in appreciation of his services as honorary instructor.

WE are informed by the Jeyes' Sanitary Compounds Company, Limited, 64, Cannon-street, E.C., that Dr. E. Klein has accepted the appointment of scientific adviser to the company, and that the coefficient values (by the Rideal-Walker test) of all disinfectants manufactured by them (Jeyes' fluid, cyllin, and corporation fluids) are tested and certified before the goods leave the works.

A SURGEON'S HONORARIUM.—The Brighton guardians recently advertised for a consulting and operating surgeon to the Workhouse Infirmary at an honorarium of 50 guineas per annum. This sum was considered by many medical men to be inadequate for the services required, and a meeting of the local division of the British Medical Association was held on Jan. 12th to consider the position. As no candidate has applied for the post the guardians have now agreed to receive a deputation.

UNIVERSITY COLLEGE, LONDON.—The Page May Memorial Lectures will be delivered this year at University College by Dr. Henry Head, F.R.S., on Fridays, at 5 P.M., beginning on Jan. 26th. The subject will be "The Afferent Nervous System," and the lectures will be open without fee to internal students of the University of London and to other persons interested in the lectures who obtain tickets from the secretary of University College.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. James Lawes Perrin the testator left £2500 to the Bristol Benevolent Institution, and £500 each to the Bristol General Hospital, Bristol Royal Infirmary, Bristol Dispensary, Bristol Hospital for Women, Bristol Eye Hospital, Bristol Deaf and Dumb Institution, Royal Ear Hospital, London, and Swansea Hospital.

MEDICAL BATHS AT TORQUAY.—At the last meeting of the Torquay town council the provision of medical baths, including a swimming bath, was discussed, and it was eventually decided to erect these under expert direction at the Bath Saloons, at an estimated cost of about £15,000.

Jenkin, Esq., of Rose Cottage, Heamoor, Cornwall.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE HEALTH AND SANITATION OF TRINIDAD.

A REPORT on the Blue-Book of the Colony of Trinidad and Tobago for the year ended March 31st, 1911, has been received at the Colonial Office and laid before Parliament. It states, *inter alia*, that the present estimated population is 368,014, as compared with 273,899 ten years ago. The birth-rate for the year, calculated on the mean estimated population, was 31·8 per 1000, and the death-rate similarly computed was 20·5 per 1000. The principal causes of mortality during the year were: diarrhœa, 601; fevers, 674; phthisis, 840; enteritis, 305; bronchitis, 351; pneumonia, 367.

The reports of the district medical officers show steady improvement in the health conditions of their respective districts. No special anti-malarial works are recorded, but educational efforts have been continued, and the diminished prevalence, more especially of the graver forms of malaria, indicates a more general and intelligent appreciation of the subject of malarial prophylaxis and treatment. Many of the district medical officers direct special attention to the increasing prevalence of ankylostomiasis and to the high infantile mortality. An Ordinance has been introduced into the Legislative Council containing provisions intended to give larger powers for controlling the spread of the former disease, and a scheme for providing nurse-midwives in certain districts with the object of dealing with the latter condition is under consideration. Twelve cases of bubonic plague occurred during the year. In addition to disinfection, special scavenging, and rat destruction, inoculation with anti-plague vaccines was extensively performed. Two fatal cases of yellow fever occurred; in each case the person attacked had recently arrived in the colony. Throughout the year anti-mosquito regulations were enforced; 473 informations were laid on account of the presence of mosquito larvæ on premises, and fines amounting to £115 were recovered. In Port-of-Spain a new abattoir was opened, and a filtration plant had been added to the waterworks. No case of infectious disease was introduced into the colony from outside. A Clayton disinfector, brought into use in 1910, has been found to work satisfactorily in the fumigation of large steamers from infected ports. The death-rate of the colony shows that the climate cannot be considered unhealthy, and for the most part European residents who take ordinary precautions enjoy as good health as in colder climates, but in certain malarial districts special precautions are requisite. Observations taken at 72 different stations in Trinidad during 1910 showed a mean rainfall for the year of 82·65 inches, the average in the preceding 20 years having been only 65·9. The mean temperature for the year was 77·9°.

The two principal hospitals are in Port-of-Spain and San Fernando respectively. At the former the admissions during the year numbered 5796, the discharges 5027, and the deaths 742, the daily average of patients in hospital being 287. Of the 5027 discharged, 2195 had been cured, 2674 had been relieved, and 158 showed no improvement when discharged. At San Fernando the admissions numbered 3107, the number discharged was 2747 (614 cured, 1993 relieved, and 140 not improved), the deaths 341, and the daily average of patients 108. There are seven district hospitals maintained by the Government in the districts of Arima, St. Joseph, Tacarigua, Couva, Princestown, Cedros, and Scarborough (Tobago). Temporary hospitals are also provided at Chaguanas, Sangre Grande, and Mayaro for use when occasion requires; and two hospitals for the special treatment of patients suffering from yaws are maintained, one at Scarborough (Tobago), with 79 inmates on March 31st last, and the other at St. Augustine (Trinidad), with 135 inmates at the same date. With regard to the latter, it is noted that in consequence of the treatment of the disease by means of "salvarsan," introduced during the year, the number of the inmates, which was 212 on March 31st, 1910, had been reduced to 135 on March 31st, 1911.

The leper asylum, which is situated about two miles to the west of Port-of-Spain, contained 273 inmates on March 31st, 1911. During the year the admissions numbered 65, the discharges 31, and the deaths 34.

THE SERVANT PROBLEM.

ONE of the commonest subjects of general and plaintive discussion at the present day is the difficulties of the "servant problem." There are few indeed who have not suffered under it, and it is admittedly becoming more and more acute. One great point is almost universally lost sight of in considering the servant problem, and that is the great change in the outlook and point of view of every man, woman, and child in the country, that has gradually been coming about as a consequence of the social change resulting from the introduction of increased facilities of locomotion and communication. In olden times the times "when servants were servants," communities were more or less circumscribed, there was a smaller proportion of people able or desiring to "keep a servant," or servants, and the supply was consequently very largely drawn from local sources. The girls, as they

grew up with domestic service before them, knew at least by repute all about their prospective employers. The employer also knew, or could easily find out, all about the character, tastes, ability, and disposition of the prospective maid. In her evenings off the girl had her parents and village friends handy, and the latter, being known to "the family," had facilities afforded them for keeping up social intercourse with their womenkind in domestic service. But all this is changed. The girl who goes out to service goes away for the most part far from home and friends. She enters a household of the personalities composing which she knows nothing and has no opportunity of learning anything before making the experiment at her own risk. Other occupations now opened up to young women of the poor offer to them a release from this difficulty. As a consequence, moreover, of the very different training children of all classes now undergo, and the consequently different ideals with which they grow up, any restraint, such as is inevitable in domestic service, becomes altogether repellent. It is idle to attempt to change the conditions of domestic service to suit this latter class, but it is of the utmost importance that a well-planned endeavour should be made so to readjust them that those whose outlook on life has not materially changed may find an attractive broadening and enlarging of their own possibilities in the sphere of domestic work. Such an attempt, it appears to us, is being made by the Women's Industrial Council (Incorporated), of which the Countess of Aberdeen is President, in its Inquiry into the Conditions of Domestic Service, "the largest single industry in this country." The council has collected the alleged drawbacks to domestic service, as well as the various suggestions that have been offered for their amelioration, and grouped them into four heads as follows: (*a*) Complete absence of organisation in the trade; (*b*) wages; (*c*) disadvantages of domestic service as compared with other trades; (*d*) prospects. The honorary secretary's address is 7, John-street, Adelphi, London W.C.

STEAM COOKING.

In ordinary households, where a regular cook is not kept, it is to b feared that less care is nowadays bestowed on the cooking of meals than was formerly the case. Yet it is not too much to say that much mischief, physical, mental, and by consequence moral, results from the use of improperly cooked food. Potatoes, for instance, of old time used to be steamed in a colander, not boiled, and the starch grains were properly broken up. That took three-quarters of an hour; now they are frequently boiled, which can be done in a little over 20 minutes, but with the result that they are neither so nourishing nor so palatable, and are less digestible. The same thing applies to many articles of diet. In these gad-about days the housewife grudges the time taken for steaming, as where some articles are steamed while others are roasted, baked, or boiled, it demands her attention much longer exclusively to the cooking. If, however, all the food were steamed, this objection would not hold good, because when once steam cooking is started it can be left alone, leaving attention free to be directed to other things. There can be little doubt that most foods are rendered not only more nutritious but also more palatable by steaming than by boiling or stewing. They are lighter and the delicate flavours are better retained. We have received a little pamphlet ("Recipes for Steam Cookery," by "Helen Whyldon." Printed by Polsue, Limited, Gough-square, Fleet-street, E.C., price 1*d*.) containing a collection of recipes for steam cooking as applicable to fish, meat, vegetables, puddings, and other dishes, including much that would be of use for the invalid.

CHRISTMAS DRESSING-UP.

It is to be hoped, perhaps vainly, that school teachers, parents, and all likely to be responsible for the dressing up of children and others for Christmas performances next December will recollect and be warned by some of the terrible fatalities which occurred during the recent holidays. The inquest upon the deaths by burning of five children at Chesterfield has been concluded, and although the verdict of the jury did not assign responsibility for the disaster to any of the grown-up persons concerned in preparing the performance which ended so fatally, the tragedy will no doubt remain graven in their memories as one which might have been avoided if someone, or if all concerned, had exercised the care which the situation demanded. A score or more of children were crowded together in two small rooms to be dressed for a performance in which the costumes were of a highly inflammable character, many of them being decorated with cotton-wool, the usual cheap and easily obtainable imitation of snow. There was so little supervision that on the night preceding the disaster two of the young girls engaged smoked cigarettes while wearing dresses covered with cotton-wool, and the fatal ignition of clothing occurred when these two girls (both burnt to death) and four or five companions dressed in the same way were "playing with fire on the following evening." The only evidence available showed that apparently some of these half-dozen children in a room containing others not so engaged were throwing upon the flames of an open grate fragments of cotton-wool, one of which escaped past the fireguard and fell amongst them. Everyone knows what children are and the extraordinary fascination which such an amusement as that indicated exercises upon them. Everyone, also, should be aware of the extremely inflammable character of what is known as cotton "wool," and it must be remembered that every Christmas at least one or two inquests are recorded as being held upon fatal cases of burning through cotton-wool used to represent snow. Grown-up people, moreover, if often careless with regard to children, are not less rash where they themselves are concerned. This year we have noticed the case of a clergyman who was injured by being burnt through his beard of cotton-wool catching fire while he was impersonating Father Christmas, and an inquest has since been held at Dover upon a young lady fatally burnt while representing the same character. In her case a robe of crimson flannelette caught fire. Christmas "dressing-up" in which snow figures as a seasonable adjunct to performances are not likely to be discontinued on account of such incidents as we have commented upon, but we should have thought that their universal popularity, combined with their obvious and proved danger, might suggest to some enterprising manufacturer the desirability of devising and advertising a non-inflammable substitute for cotton-wool.

EXAMINATION FOR LIFE ASSURANCE.

We have received a communication from a correspondent enclosing a medical examiner's report for a certain life assurance company and stating that he had declined the fee of 10*s*. 6*d*. which was offered him and claimed the sum of 21*s*., which the company refused to pay. The form which our correspondent was asked to fill up was an unnecessarily long one, and although most of the questions only required "Yes" or "No" for an answer, nevertheless the number of questions might perfectly well have been lessened. For instance, the medical examiner is requested to ask the applicant no less than 37 questions in regard to possible past illnesses and symptoms! Also, if the applicant is under 21, the collateral family history of uncles and aunts may be required, the health and ages of those living, and the ages at death and the cause of death of those who have died. The form, taken as a whole, is the longest and most detailed which we have seen, and to require such a form to be filled up, together with the necessary examination of the patient, for 10*s*. 6*d*., is certainly taking an unfair advantage of the medical examiner. We consider that a fee of not less than £1 1*s*. should always be paid for examination for life assurance. The companies who offer only 10*s*. 6*d*. when the sum assured is less than a certain amount fail to realise that the time and care devoted to the case by the examiner are just as great for the small sums as for the large. If for large amounts the fee were increased to £2 2*s*. there might be some excuse on the part of the companies who offer the lower fees, but such is not the case, and we consider that our correspondent was perfectly right in demanding the full fee of £1 1*s*. Another point raised by our correspondent is that of the companies referring to the ordinary medical adviser of the applicant should it be deemed advisable. Such a course is adopted by all insurance companies, we believe, but naturally a fee should be paid for the desired information.

BOVRIL PICTURES.

We have received from Bovril, Limited, a series of bonus pictures which they have selected for the current year. The framed artist proof of "The Pilgrims," by A. A. Dixon, is an excellent reproduction; the size of this gravure is 27½ × 19 in., and the full size of the paper is 40 × 30 in. The picture entitled "An Idyll," by Paul Gervais, is very good and full of detail. The original of this was painted for the town-hall of Toulouse and was exhibited in the Salon last year; this gravure measures 14 × 20 in. These pictures, including "The Joy of Spring," by Arthur J. Elsley, will attract attention, and credit is due to Messrs. C. W. Faulkner and Co., Limited, for such artistic reproductions.

Mr. W. C. Storey.—The manager of the Exchange in connexion with the Medical Library Association, which was mentioned in an annotation last week, is Miss M. C. Noyes, 1211, Cathedral-street, Baltimore, Maryland, U.S.A.

Communications not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

We shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.

Feb. 13th–14th (London).—Central Poor-Law Conference.

March 7th–11th (Berlin).—Thirty-third Balneological Congress.

March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.

" (London).—First Congress of Pure Food and Health Society of Great Britain.

April 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—W. W. James, Stanley Mummery): at 8 P.M.

Paper:
Mr. J. F. Colyer: The Treatment of Periodontal Disease.

Casual Communications:
Mr. A. T. Pitts: Apparent Symmetrical Bifurcation of the Roots of the Upper Temporary Central Incisors.
Mr. Bertram B. Samuel: A Crowned Tooth with a Perforated Root.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—Sir John F. H. Broadbent, Bart., Robert Hutchison): at 5.30 P.M.

Paper:
Captain McCarrison, I.M.S.: The Vaccine Treatment of Goitre.

THURSDAY.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION (Hon. Secretaries—A. Manuel, F. A. de T. Mouillot): at 5.30 P.M.

Paper:
Dr. F. M. Sandwith: Bubonic Plague (illustrated by the epidiascope).

The subject being of general interest Members of other Sections are specially invited to attend.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—T. R. Whipham, H. S. Clogg, Percy G. Lewis), at 11, Chandos-street, W.: at 4.30 P.M.

Cases:
Mr. D. Drew: Five Cases illustrating the Results of Muscle-transplantation for Paralytic Talipes Valgus.
Dr. T. Thompson: Two Brothers with Hæmophilia.
Dr. E. Pritchard and Mr. S. Stephenson: Cerebellar Tumour.
And other Cases.

Paper:
Mr. P. Turner: The Radical Cure of Inguinal Hernia in Children.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Papers:
Dr. R. J. Reece and Dr. H. Bruce Low: Poliomyelitis.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Clinical Evening. Cases will be exhibited by Dr. A. C. D. Firth, Dr. F. Parkes Weber, Dr. Michels, Dr. F. S. Palmer, Mr. W. G. Howarth, Mr. E. M. Corner, and others.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—9 P.M., Clinical and Pathological Evening.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Cases and Card Specimens will be shown by Mr. A. C. Roper, Mr. A. A. Bradburne, Mr. G. Coats, Mr. R. Batten, Mr. L. Pisani, and Mr. R. A. Greeves. 8.30 P.M., Papers:—Mr. J. H. Parsons and Mr. E. K. Martin: The Action of Ultra-violet Rays upon the Ciliary Body and Lens.—Mr. A. A. Bradburne: Hereditary Ophthalmoplegia in Five Generations.—Mr. G. Coats: On Crystal-like Bodies of Radiate Structure in the Lens.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. L. Bunch: Clinique (Skin). 5.15 P.M. Lecture:—Mr. J. L. Mummery: Non-malignant Stricture of the Rectum.

TUESDAY.—4 P.M., Dr. H. Thursfield: Clinique (Medical). 5.15 P.M., Lecture:—Dr. H. Campbell: Alcoholism and its Treatment.

WEDNESDAY.—4 P.M., Mr. O. 'L. Addison: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. H. Tubby: Surgical Treatment of Lesions of the Brachial Plexus.

THURSDAY.—4 P.M., Mr. A. Carless: Clinique (Surgical). 5.15 P.M., Lecture:—Sir G. H. Savage: Medico-Legal Relationships of General Paralysis.

FRIDAY.—4 P.M., Dr. J. D. Grant: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. G. Stewart: Clinical (Lecture I.).

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of the Nose. (Lecture III.)

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Bernstein:—Blood Examination—Morphology.

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture II.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Gynæcological (Dr. A. B. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Mr. F. Trewby: The Causes of Death under Anæsthesia at the Time of Operation and After.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. B. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappell). 4.30 P.M., Lecture:—Mr. F. Trewby: The Points which Determine the Choice of Anæsthetics for Surgical Operations.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 5 P.M., Special Demonstration (or Lecture):—Mr. McGavin: Surgical.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Dr. G. Holmes: Functional and Organic Paralysis.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Thompson: Typhoid Fever in Infancy and Childhood.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. K. Sibley: Eczema.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Coccus Diseases—I., Impetigo Contagiosa; II., Furuncle; III., Carbuncle; IV., Coccogenic Sycosis.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. W. Bateson: The Study of Genetics. (Lecture II.)

FRIDAY.—9 P.M., Prof. B. Hopkinson: The Pressure of a Blow.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

WEDNESDAY.—4 P.M., Dr. M. S. Paterson: Employment of Patients in Sanatoria 4.30 P.M., Dr. D. J. Williamson: Anti-Tuberculosis Dispensaries.

FRIDAY.—4 P.M., Prof. R. P. Williams: Open Air Schools (illustrated by lantern slides).

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. W. J. S. Bythell: The X Ray Diagnosis of Œsophageal Obstruction, with Fluorescent Screen. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.

MONDAY.—4.30 P.M., Dr. E. S. Reynolds: Banti's Disease and Hodgkin's Disease.

FRIDAY.—4.30 P.M., Mr. J. W. Smith: On the Result of Some Operations on the Stomach.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (24th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (25th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (27th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Jan. 17th, 1912.

The following journals, magazines, &c., have been received:—Journal of State Medicine, Proceedings of the Royal Society, Bulletins et Mémoires de la Société de Radiologie, International Journal of Surgery, Archives de Médecine et de Pharmacie Militaires, La Clinique Ophtalmologique, Revue de Gynécologie, London Hospital Gazette, British Journal of Dental Science, Probe, Indian Medical Journal, Practitioner, Women's Industrial News, Monthly Cyclopædia, Indian Medical Gazette, Public Health, Annales des Maladies des Organes, Génito-Urinaires, Journal of Laryngology Rhinology, and Otology, Northwestern University Bulletin, Symons's Meteorological Magazine, American Journal of Gastro-enterology, St. Paul's Medical Journal, Critic and Guide, Hospital Gazette, L'Hygiène de la Viande et du Lait, Albany Medical Annals, Archives of Pediatrics, Canadian Journal of Medicine and Surgery, Philippine Journal of Science, Military Surgeon, Maryland Medical Journal, Clinical Medicine, Malay Medical Journal, Universal Medical Record, American Journal of Obstetrics, Archives Internationales de Neurologie, Medical Review, Annals of Tropical Medicine and Parasitology, Tuberculosis, Indian Medical Record, South African Medical Record, Transactions of the Society of Tropical Medicine and Hygiene, Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris, Journal of Anatomy and Physiology, and St. George's Hospital Gazette.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. T. E. Atkins, Lond.; Anglo-American Pharmaceutical Co., Croydon; Dr. S. W. Aiken, Muskogee, U.S.A.; Mr. Thomas Allen, Box; American Medical Association of Vienna, Secretary of; Dr. John Alcindor, Lond.; Mrs. Hubert Agar, Highworth; *American Journal of Clinical Medicine*, Chicago.

B.—Messrs. Blundell and Rigby, Lond.; Brentford Union, Clerk to the; *Barrow News*, Manager of; Bristol Royal Infirmary, Secretary of; Dr. C. H. Benham, Hove; Dr. D. A. Belilios, Wimbledon; Mr. Richard Bevan, Lond.; Miss M. S. Barwell, Great Yarmouth; Messrs. M. J. Breitenbach Co., New York; British Medical Association Reform Committee, Lond., Business Manager of; Messrs. Burroughs, Wellcome, and Co., Lond.; Dr. Joseph Beard, Carlisle; Dr. P. B. Bennie, Melbourne; British Diamalt Co., Lond.; Mr. F. A. Brockhaus, Lond.; *British Journal of Nursing*, Lond., Editor of; Sir George Beatson, Glasgow; Dr. J. F. Briscoe, Alton; British Medical Benevolent Fund, Lond., Hon. Secretary of; Mr. J. A. P. Barnes, Lond.; Mr. E. Bougault Paris.; Dr. F. G. Bushnell, Hove.

C.—Mr. F. W Clarke, Chorlton-cum-Hardy; Messrs. J. Clark and Son, Devonport; Cork Chemical and Drug Co., Manager of; Mr. H. A. Collins, Lond.; Dr. R. A. Campbell, Dumfries; County Chemical Co., Birmingham; Messrs. Matthew Clark and Sons, Lond.; C. R. G.; Lieutenant Colin Clarke, R.A.M.C., Malta; Mr. W. B. Croskery, Eckington; Professor John Cowan, Glasgow; Mr. J. F. Colyer, Lond.; Messrs. J. and A. Churchill, Lond.; Messrs. Cowie and Co., Lond.; Messrs. Cassell and Co., Lond.

D.—Messrs. W. Dawson and Sons, Lond.; Mr. T. Dixon, Lond.; Decimal Association, Lond.; Mr. A. E. Downing, Albany, U.S.A.; Messrs. Duncan, Flockhart, and Co., Lond.; Dr. Dunn, Uppingham; Denver Chemical Manufacturing Co., Lond.; Mr. Kenelm H. Digby, Bowdon.

E.—Dr. Robert Edwards, Carlisle; Mr. H. Elliot-Blake, Bognor; Dr. C. C. Easterbrook, Dumfries; E. G. M.; Messrs. Elliott, Son, and Boyton, Lond.

F.—Dr. Fieldhall, Lond.; Dr. Ninian M. Falkiner, Dublin; Fellows Co. of New York, New York.

G.—Dr. J. G. Gordon-Munn, Norwich; Messrs. R. W. Greeff and Co., Lond.; Gloucestershire Royal Infirmary, Gloucester, Secretary of; Mr. S. Goldstein, Lond.; Messrs. Garland-Smith and Co., Lond.

H.—Mr. A. J. Harmer, Lond.; Hackney Union, Clerk to the; Mr. B. Herder, Freiburg; Dr. George Herschell, Lond.; Dr. Bernard Hollander, Lond.; Hospital for Sick Children, Lond., Secretary of; Hospital Almoners' Council, Lond., Secretary of; Dr. W. G. Harnett, Hadley; Home Office (Factory Department), Lond.; Dr. Leonard K. Hirshberg, Baltimore; Dr. Stuart Hallows, Lond.; Dr. Leonard Hill, Loughton; Mrs. Howard, Buckhurst Hill; Home Office, Lond.; Prof. W. D. Halliburton, Lond.

J.—Jaeger Advertising Office, Lond.; Dr. G. J. Jenkins, Lond.; Dr. W. P. Johnstone, Maraisburg; J. B.; Messrs. J. F. Jones and Co., Paris.

K.—Messrs. R. A. Knight and Co., Lond.; Messrs. Kutnow and Co., Lond.; Dr. F. Kennedy, New York; Kilmarnock Infirmary, Secretary of; Messrs. D. J. Keymer and Co., Lond.; Messrs. C. Knight and Co., Lond.; Mr. Skene Keith,

L.—Professor R. F. C. Leith, Birmingham; Leicester Infirmary, Secretary of; Mr. Kundig, Geneva; London (Royal Free Hospital) School of Medicine for Women, Secretary of; Messrs. Lloyd and Co., Lond.; Rev. W. A. Liston, Govan; Messrs. R. Lane-Hall and Co., Lond.; Mr. H. K. Lewis, Lond.; Dr. Arthur Latham, Lond.

M.—Dr. J. D. McLeod, Dallas, U.S.A.; Messrs. W. R. Magrath and Co., Leamington Spa; Dr. A. B. Mackey, New York; Dr. John McElroy, Belfast; Dr. D. M. Macdonald, Leven; Messrs. Macfarlane and Robinson, Wolverhampton; Messrs. J. Maxwell and Sons, Dumfries; Mr. R. Mosse, Berlin; Dr. Sydney Messulam, Manchester; Mr. E. Merck, Lond.; Messrs. Meister, Lucius, and Brüning, Lond.; Maltine Manufacturing Co., Lond.; Dr. Dan McKenzie, Lond.; Dr. F. J. McCann, Lond.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Mr. W. J. W. Nicol, Lond.; Dr. J. B. Nichols, Washington; Dr. David Newman, North Berwick.

O.—Oxford County Asylum, Littlemore, Clerk to the; Oxford Medical Publications, Lond.

P.—Messrs. Peacock and Hadley, Lond.; Mr. R. Parker, Liverpool; Mr. D'Arcy Power, Lond.; Mr. W. Purdy, Eastwood; Dr. W. T. Prout, Liverpool; Dr. J. Wilson Paton, Bath; Dr. D. D. Paton, Tolleshunt d'Arcy; Miss Powell, Worthing; Mr. F. T. Pain, Lond.; Prince of Wales General Hospital Lond., Secretary of; Dr. Charles Porter, Johannesburg; Messrs. C. Pool and Co., Lond.; *Philippine Journal of Science*, Manila.

Q.—Quick Laboratory, Cambridge.

R.—Roborat Co., Lond.; Royal Surrey County Hospital, Guildford; Messrs. Rogers, Bristol; Royal Waterloo Hospital for Children and Women, Lond., Secretary of; Ransom Sanatorium, Nottingham, Secretary of; Dr. Henry Rundle, Southsea; Dr. W. Ritchie, Glasgow; Mr. W. Ramsay, Melbourne; Royal Ear Hospital, Lond., Secretary of; Mr. O. Rothacker, Berlin; Dr. W. Robinson, Sunderland; Royal Meteorological Society, Lond.; Mrs. Grace Roche, Lond.

S.—Scholastic, Clerical, and Medical Association, Lond.; Dr. A. Wood Smith, North Berwick; "Scout" Motors, Salisbury, Manager of; Mr. J. D. Stewart, Cardiff; Sirdar Rubber Co., Lond.; Salford Royal Hospital, Secretary of; Mr. G. A. Stephen, Norwich; Dr. Edmund M. Smith, York; Society for the Relief of Widows and Orphans of Medical Men, Lond.; Selborne Society, Lond.; *The Standard*, Lond., Editor of; Dr. H. Scurfield, Sheffield; Professor W. Stirling, Manchester; Dr. H. E. S. Stiven, Cairo; Messrs. Spiers and Pond, Lond.; Mr. W. J. Southcombe, Lond.; Dr. W. L. Storey, Belfast; Sunderland Infirmary, Secretary of; Deputy-Inspector-General H. S. R. Sparrow, R.N. (retired), Liverpool.

T.—Messrs. J. Travers and Sons, Lond.; Dr. John C. Thresh, Chelmsford; Mr. F. Topic, Prague.

V.—Veterinary Director-General, Ottawa.

W.—Mr. C. B. Wagstaff, Leigh-on-Sea; West Ham and East London Hospital, Secretary of; Workington Corporation, Town Clerk to the; Winox, Ltd., Lond.; Messrs. J. Woolley, Sons, and Co., Manchester; Dr. W. B. Warrington, Liverpool; Dr. Charles E. Woodruff, Nagasaki; Dr. Wu Lien Teh, The Hague; Captain T. S. B. Williams, I.M.S., Lond.; Warneford Hospital, Leamington, Secretary of; Dr. G. F. C. Wallis, Shrewsbury; Dr. W. Hale White, Lond.; Mr. A. Wander, Lond.; Dr. W. Watkins-Pitchford, Johannesburg; Wackernagel'sche Verlagsanstalt, Basel; Dr. S. Wallace, Skegness; Dr. G. T. Western, Lond.; *Wessex Associated News*, Salisbury, Manager of.

Y.—Messrs. R. Young and Co., Glasgow.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. M. R. Amorin, Oporto; Mr. C. O. Aspray, Norwich; Dr. W. G. Anderson, Coehill, Canada; Mr. J. A. Angus, Falmouth; A. H. L.; A. R. H.

B.—Dr. P. Barjorjee, Garikhata, India; Messrs. Burgersdijk and Niermans, Leiden; Messrs. Blinko and Son, Ramsgate; Messrs. J. L. Bullock and Co., Lond.; Mr. T. B. Browne, Lond.; Mr. E. Dykes Bower, Gloucester; Bradford Union, Clerk to the; Mr. W. G. Bott, Lond.; Sir John Broadbent, Bart., Lond.; Dr. H. J. D. Birkett, Southsea; Dr. G. D. Barton, Weybridge; Dr. A. Bronner, Bradford; Mr. B. Bysack, Khetri; Brighton and Sussex Medico-Chirurgical Society, Librarian of; Messrs. J. Beal and Son, Brighton; Messrs. Baker Bros., Lond.; Mr. W. Bryce, Edinburgh; Mr. N. D. Buchanan, Peterborough, Canada; Mr. H. E. Blackwood, Liverpool; Messrs. J. Eade Butt and Sons, Brighton; Mr. H. Butterfield, Northampton; Dr. J. Barnicot, Hitchin; Dr. H. Beckett-Overy, Lond.

C.—Dr. R. Clapp, Whitchurch; Dr. G. Cockcroft, Middleham; Mr. E. Ceccopieri, Florence; Mr. J. Crowley, Ballycastle; Coton Hill Lunatic Asylum, Stafford, Secretary of; Mr. P. J. Clark, Lond.; Dr. J. Cooke, Lincoln, New Zealand; Mr. J. D. Chandhri, Glasgow; Dr. F. Charlesworth, Zanzibar; Mr. A. M. Cato, Lond.

D.—Dr. W. T. Dougal, Pittenweem; Doncaster Royal Infirmary, Hon. Secretary of; Derby Corporation, Accountant to the; Mr. F. W. Daniels, Newport, Monmouthshire; P. E. Derrick Advertising Agency, Lond.; Mr. T. Donaldson, Selukwe, Rhodesia; Mr. A. Donnamette, Paris; Professor A. Deschine, Moscow; Durham University College, Newcastle-on-Tyne, Secretary of.

E.—Dr. E. H. Embley, Melbourne; Mr. J. R. Evans, Llandilo; Messrs. Evans and Witt, Lond.; Mr. W. Edmunds, Lond.

F.—Dr. F. D. Fisher, Little Sutton; Dr. L. C. E. Forster, Alexandria; Messrs. Flint and Durbridge, Lond.; Dr. Graham Forbes, Lond.; F. F. J.; F. W.; Dr. A. Fleming, Lond.

G.—General Post Office, Lond., Accountant-General to the; Mr. H. Bellamy Gardner, Lond.; Mr. W. Gough, Leeds; General Apothecaries' Co., Lond., Secretary of; Mr. H. Tyrrell Gray, Lond.; Mr. L. Gamgee, Birmingham; Dr. S. Gill, Liverpool; G. G. C.; G. B.

H.—Dr. R. Henry, Poulton-le-Fylde; Haydock Lodge, Newton-le-Willows, Secretary of; H. B.; Dr. R. Hannah, Birmingham; Dr. E. R. Hunt, Brighton; Mr. G. H. Hunter, Haughley; Messrs. A. Heywood and Son, Manchester; Mr. W. H. Hosking, Masterton, New Zealand; Sir A. B. Hepburn, Preston Kirk.

I.—International News Co., Lond.

Walker, Leeds; *Winsford and Middlewich Guardian*, Winsford; Dr. H. Wise, Poynton; Dr. W. W. White, St. John's, Canada; Dr. A. T. Waterhouse, Oxford; Dr. V. Wanostrocht, Shrewsbury.

A Lecture
ON
THE MENTAL PROCESSES IN SANITY AND INSANITY.

Delivered at the Medical Graduates' College and Polyclinic on Dec. 14th, 1911,

BY T. CLAYE SHAW, M.D. LOND., F.R.C.P. LOND.,

EMERITUS LECTURER ON PSYCHOLOGICAL MEDICINE, ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—Whenever we try to prove a person insane, whether for purposes of certification or for any other reason, we endeavour to elicit the presence of actions which are at variance with the best interests of himself and the community, and if possible the presence of delusions or false ideas, not because they are of necessity the only stigmata of unsoundness of mind, but because they afford the most manifest and the most easily appreciated reasons for appealing to the friends, or possibly to a jury, who want to be satisfied that justice is being done and the law complied with.

MENTAL PROCESSES IN INSANITY AN ORDERLY DISARRANGEMENT.

Let us try to enter, if possible, into the mind of the lunatic, to see if there is really any mystery in the condition, any process of action different from that of the ordinary thinker who is said to be in his right mind, or whether, when a person is said to "have a screw loose somewhere" the expression is the true one, suggesting the result of a fault in the machinery, which result is, however, a necessary one, and can express itself in the only way in which it is doing.

If the connecting-rod of a locomotive breaks whilst the machine is at work we ought not to call it an accident if the line is torn up and the train derailed; we should say that such and such events are the proper results of the existing structural alteration, and that if there had been no such inconvenient manifestations there certainly ought to have been, and we look to see why they did not occur—the astonishment would be not that they did come about, but if they did not! If force of any kind is disturbed or diverted from its usual form of demonstration it expends itself in what we call vagaries, but which are really the only modes possible to the existing states of things; in fact, there is just as much order in destruction as there is in propriety, and the one acts in obedience to laws in the same way as the other does.

It matters not whether the motive power is too weak or too strong for its correlated machinery, nor whether it is the machinery itself which is defective; in the one case, as in the other, we have paralysis or destruction, but in either case there is obedience to natural laws, though the product is not that which we want. So it is with what we call insanity or disordered mental state.

The insane person is really sane in his type, he is saying or doing the only thing possible to his existing conditions, he is the exponent of an orderly disarrangement, though it happens that this ordered form of action is one that renders the individual a menace to himself or to his surroundings, and makes it necessary that he must be put out of action for a time; so we either restrain him, which is like putting on the most powerful brakes, or we shut off the motive power by placing him under conditions which starve it.

AUTOMATIC AND VOLUNTARY ELEMENTS IN THE HUMAN MECHANISM.

In dealing with inanimate objects we have an easy task—we can so alter what is wrong (i.e., what we consider undesirable) as to secure an ordered performance of a different kind; but when we come to deal with organised matter and with that force which some call life the problem is changed, because in the first place we are incomplete in knowledge of the details of the machinery, and next we know nothing of the vital principle itself.

To the inanimate world we ourselves supply the vital force which we connect or disrupt at pleasure, but with the organic system we find a combination which is only in part subordinate—a man may control his actions, but he cannot by thought limit the growth of his finger-nails nor add a cubit to his stature. In the organic world much that goes on is automatic, growth and decay proceed according to their own conditions of supply and demand, and all the individual can do is to go as far as possible in adjusting the balance, though in doing this he often fails miserably, because he has in many instances only an imperfect knowledge of the conditions which necessitate the result which he desires.

Though the human mechanism is a mixture of the voluntary and the automatic, we must bear in mind that the latter is the dominant and tends to invade the territory of the former, and this may develop to such an extent that the voluntary element is almost completely eclipsed, and it is during this process of invasion that we see the display of irregular processes—irregular, that is, in so far as they present a condition which is undesirable and inconsistent with the welfare of the individual, but perfectly law-abiding in its inception and continuance.

CONFLICT BETWEEN AUTOMATISM AND VOLUNTARY ELEMENT.

The rising conflict between automatism and control is a guide as to what is happening in the mental processes, for as control is less called upon automatism must increase. Monotony, the continuous working on the same lines, tends to reduce the whole system of nervous action to one level of automatic action, and it is only by constant change in the higher thoughts and processes that the abject slavery imposed by this disposition to automatism and habit can be prevented.

If necessary to prove this we have only to look at what goes on around us. Left to itself the world of mental and bodily processes goes on without change, just as does the rising or setting of the stars and the planets—the labourer goes through his task without a thought as to what he is doing, what has to be done now is the same as what was done yesterday, his consciousness is hardly called upon and his will is not invoked.

But this Eden of happiness, this absence of worry, is interrupted by such an interloper as education: the intervention of disseminators of ideas attempts to excite new processes which shall counteract the contented repose of automatism, and shall stir up fresh emotions and promote that restlessness which is the sign of force diverted into new paths; the friction with custom brings about uncertainty in the place of the placid restfulness of habit.

Automatism has its evils, it makes people sit still under the grinding influence of oppression, it maintains what is called "order" but what is really injustice, it is the tyranny of the strong over the weak. All the same, it is coördinated action, the observance of sequence in cause and effect, and as such it is a natural system; but when new ideas are introduced the old order is broken up, a new force arises which has to smash up old associations, to disrupt the grooved channels, to create new consciousness in the place of stale modality; and in the accomplishment of this there reigns for a time what is called "disorder," a difficulty of gauging exactly what is going to happen, because the new motives act with the irregularity of streaks of lightning, driven out of their direct course by the encounter of resistances at unknown and unexpected points, but all tending to settle down into organised courses as soon as the ways for these have been made straight.

MENTAL PROCESSES IN MEN WITH NEW IDEAS.

There is then no such thing as "disorder"; everything is regulated, and it is only our imperfect knowledge of the way in which cause and effect interact which limits our forecast of what must happen by absolute necessity. Thus, it comes about that the people whose business it is to cultivate individualism and destroy automatism are those who least know their own minds; by their very perseverance in inculcating their new dogmas they but form habits for themselves, they tend to develop monoïdeism, which from its refusal to entertain antagonistic arguments does but, after all, consolidate them into a settled process which is nothing but a new automatism.

What a state of unrest, then, is that of the man who is always seeking to form new associations and new channels of outlet for his compelling personality! For him there is no stability; he is buffeted about by this or that new concept which in its efforts to materialise itself, to make itself an applicable asset, sets up much internal commotion in the

agent; it makes him mysterious and, at first, unintelligible, often misjudged and repudiated, and though he may eventually be proved to be correct he must pass through a period of probation, during which the new tracts of his teaching are opened up and the disturbed automatism of his hearers has to adjust itself to new obligations.

So it comes about that the genius, the man of new ideas, the man who has to *think* and to feed the market of indolent inertia with the element of disturbance, must be in a constant turmoil, dissatisfied and progressive, apt to break down under the strain of his *vis viva*, and will be often referred to as a faddist or an irresponsible partisan. When these promoters of new ideas are successful in adding to the happiness, the health, and the prosperity of those sections of humanity with which they come in contact they are called saviours of society, benefactors, and humanitarians; when they fail they are called cranks and lunatics; but in either case the machinery is correct in its action, though it may be diverted from the mode most desirable in certain interests.

CONSIDERATION OF PARADOX: "THERE IS NO SUCH THING AS INSANITY."

You may have heard the paradox that "there is no such thing as insanity." In a sense this is a perfectly true statement. An "insane" act, an "insane delusion" is the necessary result, and the only one possible in a given state; there is then no "insanity" in it, the "insanity" would be if what is viewed as disorder did *not* happen. To call that "insanity" which is nothing but the necessary action of a certain combination is a misuse of terms; it is applying to the one part of a whole process a term which if used at all should be confined to the primary agent of the inevitable course which we deplore.

Suppose a man who has the delusion that he can arrest force at any moment drives an engine at full speed into the "stop" at a terminus station so that he may demonstrate his supposed power, we all know what the result would be; and it would be called a mad act. But the act itself is not a mad one, the madness lies in the motive; just as it would be called a wicked act if done from motive of revenge, or an act of bad judgment if done from a wrong appreciation of the laws of motion. But further, the delusion, or the wicked thought, or the erroneous judgment is itself a necessary result of certain conditions acting in the only manner possible, and as we do not understand what these conditions are we find ourselves using different terms for what may after all be the same thing.

The same mal-appreciation of the action of established law holds in general estimation of the world's past and present history—it is no uncommon thing to blame God or the Devil when death ensues upon disease or in catastrophes. If a miner takes off the cap of his safety lamp to light his pipe an explosion of gas, if it is in sufficient quantity, follows—it would be wrong if it did not.

We cannot live on the continual exhibition of miracles, nor can we expect that supplication to the Powers above or below will enable us to fire a shot unless we keep the powder dry. What we want to arrive at is, then, the cause which sets the machinery of action on the wrong track—it may be a flaw or defect of the mechanism, or it may be in the motive power itself, and this it may be quite out of our scope to subordinate and direct.

DIFFERENT VIEWS ON PSYCHOLOGY.

Much depends upon the views we adopt in our psychology. If we are of the school which recognises an apperceptive process, a will-power, a spiritual element, we are to all purposes impotent. If we do not know what will-power is, how are we to control it, where to begin, or what agent to employ to counteract excess or to stimulate flagging energy? All we can do is to pray that our courses may be directed in the right grooves.

If, on the other hand, we belong to the material school which says that the body contains in itself all that is necessary for its own government, which repudiates a conative factor outside existing and internal bodily processes, rejecting such agents as will, spiritual side of mind, power of attention, &c., reducing in fact the action of mind to integrity of bodily processes, then the matter may be easier to understand, because the man who is acting strangely is doing so because of some structural alteration which we may be able to remedy; whereas on the alternative theory we may be paralysed in diagnosis or treatment because we have no fulcrum on which to place the lever.

Evidently it is very important to settle which of the two theories is correct, for until it is decided a science of mental diagnosis and therapeutics is out of the question. The truth lies probably in a combination or interaction of the two theories—that which at first required a directing agency becomes at last independent, acts automatically, and comes to a greater extent under handling, but there still remains the inscrutable agency which (according to many) we cannot materialise, which, for aught that is known, is capricious in its selections and its processes, though if it exists it must be obedient to laws of its own with a scope of action on settled lines from which there is no straying.

Whoever can in a convincing way show which is the true theory or the nature of the immaterial conative process—if there is one—will have solved the mystery of ages and opened up the secret ways to the stronghold which we in the present day can no more nearly approach than could the philosophers of old. I am not forgetting that the clergy say that the problem is already solved, but even if we acknowledge that we must accept authority and believe in the existence of a "spiritual body," let it still be remembered that it remains at that, and nothing of its real nature or action is available to us.

NATURE OF DELUSIONS.

If we examine closely the nature of the delusions in a person who is in delirium or in the acute mental disturbance which is called insanity, we note that they are especially connected with the most recent topics, matters that have not had time to become automatic, such as political and social events of great urgency at the moment, murders, strikes, big functions and celebrations, aeroplanes, prominent personages, whilst the old ideas and acts which have formed the automatic life of the patient, those which are indeed his character, are in the background or not conspicuously prominent. I do not say that the old storehouse of thought and conduct is never invaded, but that it is much less frequently so than the newer tracts, perhaps because having become automatic they are less likely to be affected by transitory causes, they are more resistive to interference.

It is in the order of things that these prominent and compelling new ideas express themselves in connexion with the language areas, and should therefore issue with a volubility proportionate to their intensity, and, moreover, it must follow that the patient hears what he says, and his attention is called to the action of these speech-centres until at last he comes to believe in what he hears, and acts upon it.

In all this there is nothing abnormal nor different from the ordinary mental processes. All of us act in the same way—we have our ordinary, or even new, ideas which connect themselves with speech-expression, and draw our attention more or less according as they are new or old. The only difference between the sane and the insane person is that the latter cannot arrest or change the current of his processes, whilst the former can; the latter has lost his brake-power, but the former retains it—the latter is helpless either because the driver is incapacitated and cannot make use of the machinery, or else the brake itself is unfit to act upon structures which it is now unable to control, and so the new state will go on until some change is brought about which shall restore the old necessity—the new necessity may mean ruin, desolation, and disorder, but it is what we expect, and should be surprised at if it did not follow.

The clue, then, to what is going on in the mind of an insane person is to be found by following up his speech and actions until we arrive at the ultimate state which alone could cause them, for there the trouble lies, and not in the manifestations which set up so much alarm, but which are really nothing but danger-signals—and this eventually comes to an inquiry into motives.

SANE AND INSANE MOTIVES.

It is not always easy to say what is a sane and what an insane motive, because either may issue in the same external process.

For instance, a simply wicked person, being desirous of securing some result advantageous to himself, deliberately plans a murder and realises it. The insane person is the victim of an internal process which sets in action the same intermediary processes as those which would be used if the

action were one of free will. There is, however, this difference between the two, the insane person, as long as the condition lasts, must act in the direction of his compelling ideas, the sane but wicked person has his ideas in check; he can dispose them as seems most fitting for his ultimate ends; the former is a compelled agent who just does what he has no power to prevent and does it utterly regardless of the surroundings, the latter is a discriminator who chooses his time and methods.

CONDUCT OF A LUNATIC.

We can never forecast what will be the conduct of a lunatic because we cannot tell what may become primary and compelling motives, but if we have a clue given as to the nature of his conversation and his acts we can often argue back to the necessary idea which is the complement of the process and thus obtain a connected chain of the whole series of events. In many ways the insane person acts against his own interests—he must do so—his compelled ideas express themselves in words against his true interests, he reveals his life the details of which he has hitherto kept secret, he accuses himself of crimes which he has never committed, he actually does things which rush him on to self-immolation or the sacrifice of others, and all because some temporary internal process touches off some arrangement, releases a coiled-up spring whose potential energy was never intended to be started by caprice.

It is not an uncommon thing to find after stirring social cataclysms, such as emotional revivals or startling murders, that ordinary persons come forward and accuse themselves of the commission of crimes which it is afterwards proved they could not have done. You can never trust a lunatic or a person under the influence of strong emotion, for this reason—viz., that the processes in action are identical: the former is under the stress of an idea which is more or less constantly working out its own career in its own way; the latter is for the time (it may be momentary) under the impulse which unravels itself in the way easiest open to it, and the only difference between the two individuals is in the persistent or the temporary condition of the exciting motive—the processes of exposition are the same.

PROMINENT MENTAL PROCESSES IN THE INSANE.

To think continually in a certain way is to imitate the process which is going on in the insane person. A sane person who is in the habit of saying that he has done such and such a thing is apt to believe, when in reality he has not, at last that he really has so acted. Of course, he is at the first a liar, and he knows that he is; but from constant repetition the knowledge that he has *not* fades before the persistent iteration that he *has*, so that at last, coming to believe and even to act upon the belief, he ceases to be a liar and is just an automaton. I find no difference between his mental process and that of the lunatic.

ALTERATION OF INTENSITY OF EMOTION.

The other prominent mental process in insanity is alteration in the intensity of emotion. Of the exact nature of emotion or feeling we are ignorant, but perhaps the way of looking at it which best serves us is to view the process as a sort of tone mixed up in an intimate way with certain ideas—thus ideas of wealth, of success, of relationship with certain individuals have a pleasant emotional tone; and ideas of loss, of danger, of injury, of anger, of moral wrong, have an unpleasant emotional tone. Further than that we do not seem able to go; anyhow, it is enough for our present purpose.

It follows as a necessary consequence that the re-excitement of ideas which already have a structural basis must at the same time re-excite the emotional tone. But individuals vary much in the intensity of the emotional tone associated with an idea; apparently the same idea will in one person be associated with a moderate amount of pleasure, grief, or anger, whilst in another the equivalent idea will be attended with an extraordinary outburst of enthusiasm, grief, or revenge. And it is not easy to say what is the special determinant of these two phases.

Emotion (as the etymology of the word implies) is the great determinant of action. It is very strong in enthusiasts and faddists, and often leads them to extravagance of conduct and diction in the accomplishment of their ideal; on the sexual side it occasionally ends in murder or suicide, in the latter case a jury gives the victim the benefit of the doubt, and says that he was in a state of temporary insanity, in the former it sends him for trial and very often executes him.

A man with ideas of persecution (which may be true in fact) takes steps to assault or to rid himself of his persecutors, and for a demonstration in this direction he is penalised by the law; an insane person who imagines that he is persecuted behaves in the same way and comes under the cognisance of the law. So similar are the two processes that there often arises much difficulty in discriminating between them, in saying in fact which of the two is the lunatic.

EXAMPLES OF LOSS OF MORAL SENSE.

I suppose there is no class of persons so liable to loss of moral sense—in other words, so susceptible to emotional desire of possessing—as "collectors," especially where art treasures are concerned. I know a gentleman of great intellectual power and a well-known "collector" of curios of a certain kind. On one occasion, on attending an exhibition of curios in his own especial line he took the opportunity to purloin an article and go away with it. He was, however, noticed by an attendant, and when the next day a bill for the price of the appropriated article was sent in it was promptly paid.

Everyone is familiar with the manner in which some collectors of curios, bric-à-brac, and old china scour the old farmhouses and cottages in the country in the endeavour to pick up a bargain. The poorer the owner, the less hesitation has the prospective possessor to offer the smallest price, knowing at the time that he is minimising the real value of what he wants. It is a question whether such an act comes under the head of honest dealing—whether, in fact, it is not a display of normal ineptitude, a process in no way different from that of the lunatic who sacrifices moral obligation to the accomplishment of impulsive desire.

HOW THE REAL CHARACTER OF MAN IS KNOWN.

There is nothing new in modern thought; we think and act in the same terms as did our ancestors, and we only know the real character of men by the results of the action due to emotional tone. What the insane man really teaches us is the mind of to-day; he lays bare without hesitation his mental processes, and, therefore, we know him; but the mind of the ordinary man we do not know until he comes under the influence of the same processes as the insane person, and this he does when through ambition, personal or altruistic aggrandisement, he says what when the impulsive state has passed he either does not remember or denies. It is a kind of sane-insane action; and remember that the insane person is usually a compound of processes.

Consider the case of the ambitious man—it matters not in what walk of life; he is absolutely monoïdeistic, nothing is allowed to stand in his way, an end has to be compassed, and he is ruthless in his processes of accomplishment. He becomes selfish and unpatriotic. What is it to him that the feelings and the interests of others suffer! In his eagerness for self-advancement he overrides the scruples of the cautious, whom he nicknames timid and retrograde. Everything must go down before his leaping egotism. He recks not the warnings and supplications of the downtrodden necks over which he steps to the realisation of his goal. His function is to crush more and more, and still to keep on crushing until he has raised a mangled platform upon which he may celebrate the triumph of his obsession.

Another man, under the idea that he is all-powerful, does his best to assert his position. As far as he can he lays his plans so as to demonstrate his superiority; he destroys what interferes with or tries to check his self-aggrandisement; and it is no more to him than it is to the ambitious one that suffering and destruction strew the path over which he passes.

What is the difference between the mental processes of these two men? None that I can see, except that the one tries to keep his goal, the other to attain one. Yet the one is called insane and no attention is paid to him, whilst the other suns himself with equal self-satisfaction in the flattery of his friends or the curses of his victims.

It is often difficult to understand politicians. We think that they are dissembling owing to the exigencies of party politics. But now and then they are led by emotional or by environmental stress to say what they did not intend; they let themselves go, and then their true nature is revealed. We

know what manner of man they really are; their temporary loss of control has unmasked them.

PSYCHOLOGY OF WAYS OF CELEBRATING GREAT OCCASIONS.

Consider for a moment the psychology of our methods of celebrating great occasions. Truly we are of conglomerate formation! We notify our times of excitement and depression in either a constructive or a destructive fashion. On the one hand, we erect statues, establish memorial homes, or build hospitals or churches, to be the vicarious expressions of the prevailing emotions. On the other hand, we celebrate the event by acts of destruction. We do not go so far as to immolate our weaker kind nor even to make the sacrificial offering of bullocks and rams, but we do vent our energy on inanimate objects. We burn tons of gunpowder in fireworks and artillery, we disperse millions of electric units in illuminations, we consume forests of wood in bonfires, we slaughter thousands of cattle and fowls for feasting and revelry.

ROMAN AND MODERN METHODS OF PUBLIC REJOICING.

A Roman Emperor held public butcherings of gladiators, whilst we content ourselves with mimic naval and military displays and athletic strife of a more peaceful character, but still we promote lavish expenditure of money in display of dress and pageantry, we gorge the thoroughfares to a dangerous extent by whetting the curiosity of unmanageable crowds, and we are only satisfied when the cauldron of excitement is kept seething for hours until the whipped-up energy exhausts itself and fizzles out from sheer expenditure of substance.

The cooler moments of evolved civilisation have made it clear that cruelty and destructiveness are not legitimate modes for the working-off of excitement, but they have taken into account the fact that human nature is at root much the same as it ever was, and that if the display of it is to be prevented force has to be used and the nascent trend of excitement must be nipped in the bud by the law.

Surely some of these demonstrations look like the acts of madmen; indeed, if we saw madmen doing them we should agree that they were mad acts, and yet they occur in our midst and no one accuses the perpetrators of insanity.

NEED OF CONTROL OF EMOTIONS.

Our emotions and feelings are of the greatest benefit and efficiency as causes of display of energy when they are kept within proper bounds, but they may be dangerous when not controlled; in all people there are times when they seem to get out of hand.

A suffragette, from motives of revenge because she cannot obtain what she desires and says she is entitled to, and obsessed with the idea that by acts of violence she will get attention to, and sympathy with, her cause, breaks windows and assaults authorised agents of the law. She goes to prison, refuses food and has to be fed artificially. A patient in an asylum because of a grievance smashes glass or assaults an official in order to draw notice to his case; he may refuse food from the idea that he is giving trouble, and he has to be fed artificially.

Is there any apparent difference in the processes of the two classes mentioned? None that I can see. Yet the one is held to be insane; but he would be a bold man who would postulate such a mental state of the other. You may say that lunatics often do sane acts and that sane people are at times so carried away by emotion as to act in an insane manner, but it is no more correct to call the lunatic sane because he acts as some sane people do than it is to call the others insane, because *quâ* mental processes the two cannot be distinguished.

MEDICO-LEGAL DIFFICULTIES.

Can we wonder, then, at the difficulty of lawyers and juries to say when a person is insane or not? Can we be surprised at the conflict of evidence when medical men on one side will say that the criminal is insane and others that they find no insanity in him? What has just been enunciated is the key to the whole question. There is no difference in the *processus mentis*. The public see two men act in the same way. Little wonder then that they place both in the same category. There are, certainly, differences in the two cases in the way in which the process starts, but there is no difference in the accomplishment, and the difficulty lies in finding out the prime cause which started the process. Was it one unavoidable from the condition of the machinery or was it deliberately brought about by the controller of the mechanism?

It was this diffiulty of reconciling opposing opinions as to the interpretation of symptoms which first led me to the conclusion that such confusion is the natural result of action, especially in nervous complaints, where the mechanism is so inaccessible to direct observation, and where the physiological, chemical, and pathological conditions of action are as yet so imperfectly known and indeterminate.

See what happens in the trial of cases of surgical neurasthenia in the law courts. There may be agreement on both sides as to the symptoms, the subjective statements of pain or incapacity for work, &c., but whilst one medical witness characterises the whole group of objective symptoms as a sham, an acted lie, the other affirms his belief in the truth of what the patient says and in the existence of actual disease. And yet each may be sincere in his convictions.

It cannot, then, be wondered at that juries are puzzled and experts blamed when absolutely contradictory statements are made and judgments founded upon what is really an incomplete investigation—i.e., the courses of processes which use the same rails but have different starting points. The juries see that the process of travel is the same in the two cases, and the experts cannot explain the difference in the diverging centres.

MENTAL PROCESSES IN CRIMINAL ACTS.

At the International Congress on Psychology held at Amsterdam on Sept. 3rd, 1907,[1] I read a paper on the Analysis of the Mental Process in Criminal Acts, in which the following occurs:—

> My position is that in criminal acts the mental process introduces no fresh element. The constituents of the voluntary process are the same in kind as in normal minds: motive, desire, feeling, end in view, action on presentation (otherwise impulse), action upon reflection (volition)—all may occur in the same way as normal thought processes.
>
> The only difference is not in the mechanism of the elements but in their nature; thus the motive may be a wrong one (i.e., against the accepted obligations of society), or the element of feeling may be an irregular one due to structural conditions, but we must remember that just as social systems are temporary—are themselves in an unstable condition—so are mental processes.
>
> We have not in the one the perfection of organisation, though such as it is it acts in accordance with its construction; neither have we in the other any but a temporary adaptation, though such as it is it acts in the way we should expect it to do, and in this expectation we are rarely disappointed.

These views have not been challenged, and I see no reason now for changing them; on the contrary, a better comprehension of them must elucidate what has hitherto given rise to somewhat truculent remarks about the integrity of those who are ranged on opposite sides in the forum.

TOLERANCE OF SOCIETY BEFORE IT CONFINES PRISONERS AND LUNATICS.

What then, you will ask, is it that makes it necessary to restrain people and confine them under certificates if their processes are of the same order as that part of the population which is allowed to go about free? The answer is that society protects itself, either by the prison or the lunatic asylum, when the acts of individuals are contrary to law, and are therefore dangerous to the integrity of the social system.

Society is very tolerant; it puts up with a good deal of wrong action and condones it because it is not always easy to bring out the whole of the process that leads to what is felt to be injurious. We have lots of thieves and lunatics in our midst, but we do not interfere with them up to a certain point; and even when that point has been reached we only employ temporary measures in the hope that the cause of the militant processes may be stayed or obliterated. Only in the extreme instance of murder do we consider the necessity for total extinction of the unit.

VAGARIES OF APPARENTLY NORMAL PERSONS.

Perhaps it is not overstating the case to say that no one's nervous system would come out unscathed from a searching microscopical, chemical, and physico-experimental investigation, and if so there must be actions which we cannot account for. As it is, we cannot account for much; we can only to a very limited extent understand the nature of nervous action.

The vagaries of even those generally considered to be level-headed people, the actions which neither we nor themselves can account for, are they the result of the imperfect

[1] See THE LANCET, Nov. 9th, 1907, p. 1306.

structure above hinted at, or are they the results of an agency which is swaying the material in a manner in harmony with itself, whose very existence is for us only a conjecture? For at present mind, soul, spirit are to us nothing but terms for the intangible.

There are many who deny the necessity for these new developments of thought—they say we have all that we require. On the other hand, if we have progressed from inorganic to organic, why may we not further develop into the spiritual, unless the spiritual is something entirely different from the material as we know it?

What is the Life principle? Is it different in a fish or an elephant from what it is in a man? The material for investigating life is with us, but we cannot isolate it, we cannot take it away and put it back, we do not know where to begin to tackle the problem, because, as far as we know, there is no simplest form of it—it is there from the first in perfection and entirety.

CONSIDERATIONS ON THE OCCULT.

Nearly two years ago in this very room I lectured on "Considerations on the Occult," and in the lecture I said:—

> Is there going on outside us a world of *Force* which requires for its display the human mechanism? If there is Force existing under these conditions does it ever show itself in apparently purposeless actions, such as eccentricities of conduct and impulsive words and deeds which can neither be explained nor accounted for?

If there are external forces which are able to affect the human mechanism it is surely not possible to deny that an individual may be moved to speak or to act in a way unknown to himself by some influence of which he is the appropriate medium. Viewed thus man is a necessary complement of this force, and one object of his creation is merely that of a force-terminal, an Æolian harp which discloses the motion of winds which cannot be seen.

At the British Association meeting for the year 1911 Professor J. S. Macdonald, President of the Physiology Section, said:—

> Whilst there was no scientific evidence to support or to rebut the doctrine that the brain was possibly affected by influences other than those which reached it from the sense-organs it was still possible that it was an instrument traversed freely by an unknown influence which found resonance within it.

You are entitled to ask, How will such a theory fit in with the subject under discussion? Viewing the brain as a mass of matter involved in certain physical and chemical states it is evident that the more it is educated the more complicated will be these states and the more varied the results from the influence of the sense-organs and other receptive surfaces of the body, but these results, though they imply Life, do not of necessity imply mind—i.e., soul—they may be merely nervous states which involve no Consciousness, no Will, not even Emotion, they are the same in the insane as in the sane.

It would be idle and irregular to discuss the question of the possibility of any change in the nature of the force or influence which has at present only a suggested existence, but I have endeavoured to point out that whether we argue on the monistic or on the dualistic hypothesis, the view here taken is the same—i.e., that when a criminal act is due to disease the mental process differs in no way from that of the normal state. And what is specially said of criminal acts seems to be of equal application to others.

Speculative psycho-physiologists would certainly acknowledge that, whilst speaking of the possibility of force influence, they do not mean that it is necessary for all forms of brain-action to be dependent upon it for their demonstration. The brain is certainly capable of action by itself, independently of this external force attunement, and as no one can speak definitely about the limits of concerted or of independent action, we must, for the present, leave it at that, and not be surprised because the monists maintain the integrity of their position.

SOME REMARKS ON EXPERT EVIDENCE.

In bringing to your notice, gentlemen, the subject of the similarity of brain-action in the sane and the insane I have been urged by the desire to reconcile the very contradictory opinions which are often given by experts in the law-courts, opinions which puzzle arbitrators and make them sceptical of the value of this sort of evidence.

Many of the manifestations in health and disease run in parallel lines, and since it frequently happens that observations have to be made and decisions arrived at during this career of parallelism it is easy to see that there is plenty of room for divergence of opinion as to where the symptoms started and how they will eventuate.

To have one man averring on oath that a certain person is insane, whilst another with equal conviction declares that he is not, seems to be ridiculous, but the folly is not in the disputants, but in their critics, who do not see that a number, say nine, may be arrived at by two constructive processes, either by the multiplication of three by three, or by the addition of four to five; or that it may be similarly obtained by a destructive process—e.g., by the lessening of 11 by 2.

ON THE PERCENTAGES OF ETHER VAPOUR ADMINISTERED IN SO-CALLED "OPEN ETHER" METHODS.

BY SIR FREDERIC HEWITT, M.V.O., M.A., M.D. CANTAB.,
ANÆSTHETIST TO HIS MAJESTY THE KING; PHYSICIAN-ANÆSTHETIST TO ST. GEORGE'S HOSPITAL, LONDON;
AND
W. LEGGE SYMES, M.R.C.S. ENG.,
UNIVERSITY DEMONSTRATOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON.

THE very satisfactory results obtained by the former of us during recent years with a particular method of anæsthetisation, in which so-called "open ether" has played an important part, have led us to extend to ether administration some measurements by the second of us analogous to those made in connexion with chloroform [1] when administered by a Skinner's mask. Some of these measurements have already been quoted in the current report of the Anæsthetics Committee of the British Association for the Advancement of Science.[2]

The clinical method in question may thus be described. To all adult subjects a subcutaneous injection of atropine (gr. 1/100 or 1/120) is administered three-quarters of an hour beforehand, partly with the object of preventing mucous secretion during etherisation, and partly with the object of preventing cardio-inhibitory shock during those operations which are liable to excite this condition. Morphine is administered with the atropine only when the patient's reaction to this drug is known or when there is some special indication present, as recent experience has taught us that in a small percentage of cases—possibly in 1 or 2 per cent.—undesirable effects may follow upon the preliminary injection of morphine. Induction is not effected by ether as is customary in America and amongst numerous anæsthetists in this country, but either by successive drops of chloroform or C.E. mixture (2 parts of chloroform to 3 parts of ether). The best results have been obtained by starting with chloroform administered drop by drop upon a Skinner's mask, covered with one layer of flannel held loosely over the face, the administration being so gradual as hardly to be noticed by the patient. Irwin's chloroform drop bottle is specially useful in this method, as the frequency with which the drops of chloroform escape from it can easily be regulated. This first stage in the administration generally lasts about two minutes. At the end of this time, when the substitution would hardly be detected, the chloroform is replaced by C.E. mixture, the administration still being very gradually conducted by means of a drop bottle similar to the preceding. During this stage, which generally lasts another two minutes, a gauze face pad (Fig. 1, A), possessing an oval opening, is placed upon the face as shown, with the double object of protecting the face from the anæsthetic and of securing coaptation of the Skinner's mask (B) during the subsequent etherisation. At the end of about four minutes from the commencement of the administration ether may generally be sprinkled upon the Skinner's mask without the patient detecting the change of anæsthetic. Owing to the gradual invasion of the nervous system, which is possible by this method, excitement and struggling are

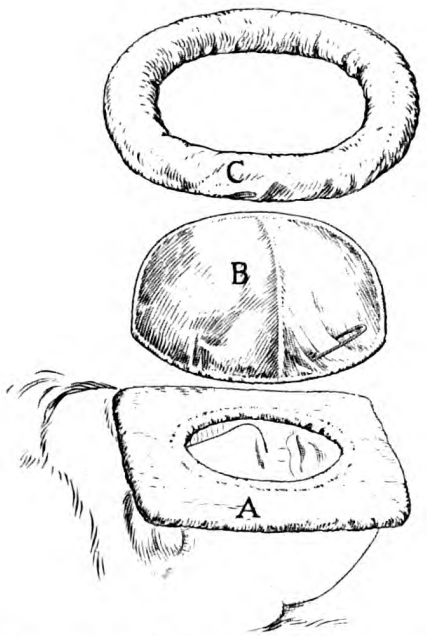
[2] Waller: On the Percentage of Ether Ordinarily Afforded by an Open Method of Administration, Report, British Association, Portsmouth, 1911.

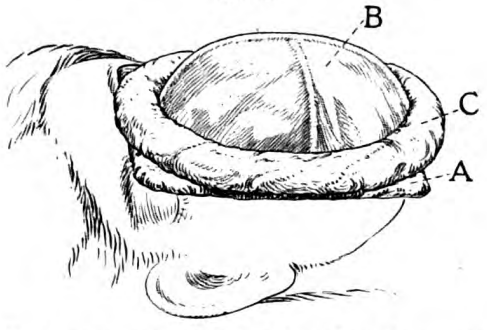
rarely met with. Any indication of excitement should be taken as the signal for the commencement of etherisation. If no such indication present itself ether may be commenced when it is judged that the patient would not detect the substitution. The mask is now kept more or less saturated with ether and the oval gauze collar (C) is placed around the

FIG. 1.



mask. This arrangement of face pad and encircling collar[3] (Fig. 2) is found to be more convenient than loose gauze for surrounding the mask, and for thus making the whole of the respiratory current pass through the etherised fabric. In order to obtain the best type of ether anæsthesia, it is generally necessary to secure oral rather than nasal respiration. Delay in obtaining this type of anæsthesia is nearly always due to the presence of inadequate nasal breathing. It is hence generally advisable before the operation is

FIG. 2.

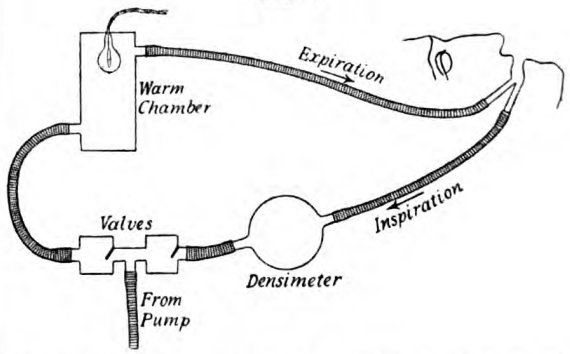


actually begun to remove the pads and mask temporarily, to open the mouth with a Mason's gag, to clear the fauces of any mucus by sponging, and to introduce either a mouth prop or the "oral airway" already described[4] by the former of us. In some subjects, and particularly in those who from the presence of throat affections are in the habit of swallowing mucus, this sponging of the fauces may excite an act of retching or vomiting. Should it do so the eventual type of anæsthesia will be far better than would otherwise be the case. By this temporary suspension of the administration, for the purpose of clearing and increasing the airway, the breathing will become so free that it will be found possible to secure and maintain full ether anæsthesia by the means described even in vigorous male subjects. If no such interval be allowed for, an unsatisfactory type of anæsthesia may be expected, at all events, in certain cases. The operation may generally be commenced in from seven to ten minutes from the beginning of the administration. Should the patient display abnormal insusceptibility to ether a temporary reversion to the C E mixture may be effected. When once full ether anæsthesia has been produced it will be found exceedingly easy to maintain it by keeping the mask thoroughly moist with the anæsthetic.

It is unfortunate that the term "open ether" should have become current to designate the plan of administering this anæsthetic which has just been described. Strictly speaking, an open method is one in which the mask loosely rests upon the face, so that both inspired and expired air can travel between the mask and the face without necessarily passing through the moistened fabric of which the mask is composed. In such strictly open methods unknown and irregular proportions of atmospheric air dilute the vaporised anæsthetic. In many cases indeed it is highly probable that the inspiratory current takes up the anæsthetic by passing over it—i.e., by passing between the mask and the face without ever passing through the moistened fabric. It would, perhaps, be more appropriate to speak of the so-called "open ether" system of administration as the "perhalation" system, for when properly applied, as in the method just described and as in the experiments below, the whole of the respiratory current passes *through* the etherised fabric. There would then be a convenient distinction between the purely open system of administration and the perhalation system. The former of us is of opinion that it is only by this perhalation system that it is possible to obtain ether atmospheres sufficiently equable and constant to be of value in clinical practice.

Our method of experiment was substantially that used in the former estimations of chloroform vapour to which reference is made in the opening paragraph of this communication—viz., to aspirate air from beneath the mask, through a densimeter bulb, adjusting the frequency (24 per minute) and volume (250 c.c.) of the aspirations to resemble those of human respiration, and to estimate the percentage of ether vapour in the bulb by Waller's[5] method of comparing its weights, when containing and when not containing ether vapour respectively. The vapour mixture aspirated from the mask was returned to it by a second tube passing through a warm chamber to imitate as closely as possible the influence of warm expired air on the evaporation, and on the distribution of the ether vapour (Fig. 3). This imitation

FIG. 3



fell short of completeness in that, unlike expired air, the mixture, returning to the mask, was not saturated with water vapour, introduction of which would have complicated the experimental work and have protracted the observations beyond the time at our disposal.

In one important detail the present experiments differ from those of the earlier series mentioned above. In the latter (chloroform estimations) the mask lay loosely over the

[3] These pads and collars, as well as the flannel Skinner's mask, may be obtained from Messrs. Allen and Hanburys of Wigmore-street. This firm also supplies the Irwin drop-bottle for chloroform or chloroform mixtures and a satisfactory form of ether bottle suitable for use in the method described.

[5] Waller: Ether Estimation by Densimetry, Journal of Physiology, vol. xxxvii., 1903-04.

aspirating (inspiratory) and returning (expiratory) tubes, whilst in the present (ether) series it was fitted as closely as possible over a model of the human face by means of the pads shown in Figs. 1 and 2. By using experimentally the very mask and pads which had been employed clinically we were thus able to ascertain with a minimum of error the percentages of ether administered in practice. The inspiratory and expiratory orifices opening into the mouth of the model are shown in Fig. 3. In calculating the percentage of ether in the air inspired by the model no allowance was made for variations in temperature or in air pressure, as such corrections, even in extreme cases, are of negligible importance. The ether[6] was poured on the mask from a dropping bottle at rates corresponding to those employed in clinical practice during the induction and maintenance of anæsthesia, and estimations were made during three stages.

Although in the clinical method already described in detail anæsthesia was not induced by ether we thought it advisable to make a few estimations of ether percentages during the induction of anæsthesia by this agent, seeing that many anæsthetists prefer to commence and continue with ether rather than to employ a sequence.

STAGE I.—*Induction by Ether.—Duration of Etherisation = 1 Minute.—Ether Added by Small Douches Every Few Seconds.—About One Half of the Mask Moistened.*

TABLE I.

Fabric.	Ether in inspired air.
Surgical gauze ... ... 4 layers.	5·4 per cent.
,, ,, ... 4 ,,	8·0 ,,
,, ,, ... 8 ,,	9·4 ,,
,, ,, ... 12 ,,	11·0 ,,
Flannel (washed) ... ... 1 layer.	6·8 ,,
,, ,, ... 1 ,,	4·0 ,,
,, ,, ... 2 layers.	5·0 ,,
Lint (new) ... ... 1 layer.	5·4 ,,

STAGE II.—*Maintenance of Anæsthesia. Whole of Mask Kept Moistened by Frequent Additions of Ether during 1 Minute.*

TABLE II.

Fabric.	Ether in inspired air.
Surgical gauze ... ... 4 layers.	11·0 per cent.
,, ,, ... 4 ,,	11·0 ,,
,, ,, ... 8 ,,	11·4 ,,
,, ,, ... 12 ,,	11·0 ,,
Flannel (washed)... ... 1 layer.	8·0 ,,
,, ,, ... 1 ,,	8·4 ,,
,, ,, ... 2 layers.	8·0 ,,
Lint (new) ... ... 1 layer.	10·0 ,,

STAGE III.—*Maintenance of Anæsthesia. Whole of Mask freely Douched during 2 Minutes.*

TABLE III.

Fabric.	Ether in inspired air.
Surgical gauze ... ... 4 layers.	12·0 per cent.
,, ,, ... 4 ,,	10·0 ,,
,, ,, ... 8 ,,	13·4 ,,
,, ,, ... 12 ,,	14·0 ,,
Flannel (washed) ... ... 1 layer.	8·0 ,,
,, ,, ... 1 ,,	8·6 ,,
,, ,, ... 2 layers.	8·0 ,,
Lint (new) ... ... 1 layer.	8·0 ,,

[6] The ether used in the above experiments was that manufactured by Messrs. Huskisson and Co., and known as "pure methylated ether." In answer to inquiries made by us we are informed that it has a specific gravity of ·719–·720 at 60° F., that it commences to distill at 76° F., and that it is perfectly free from water.

These three tables bring out the fact that, for a given dampness of the mask, the gauze yields a higher percentage of ether than the other fabrics, and that a double layer of flannel offers no advantage over a single layer. Lint and flannel behave alike. The fluctuations in Table I. were to be expected, as no attempt was made to keep any definite portion of the mask moistened. The absence of such fluctuations in Tables II. and III. is remarkable as indicating that under the specified conditions an ether percentage, sufficiently definite and regular for clinical purposes, may be relied upon. In the above cases estimations were made uniformly 10 seconds after the last douche. In the following a longer interval was allowed to test the holding power of the various fabrics.

TABLE IV.

Fabric.	Interval between last douche and estimation of ether.		
	10 seconds.	1 minute.	2 minutes.
Flannel (washed) ... ... 1 layer.	8·0% ether.	6·0% ether.	—
,, ,, ... 1 ,,	8·6 ,,	8·0 ,,	6·4% ether.
,, ,, ... 2 layers.	8·0 ,,	6·0 ,,	—
Lint (new) ... ... 1 layer.	9·8 ,,	8·4 ,,	6·4% ether.

It is of interest to note in connexion with the above figures that they confirm Professor Waller's prediction that the percentage of ether inhaled during anæsthesia would be between 6 and 16 per cent. It may be noted, however, that in the above experiments we did not obtain a higher percentage than 14. To test the value of very excessive douches the following experiments were made.

TABLE V.—*Excessive Douches, 20 c.c. (about 5 fl. drachms) of Ether Used, in a Period of 1 Minute.*

Fabric.	Ether in inspired air.
Flannel (new) ... ... 1 layer.	7·2 per cent.
,, ,, ... 1 ,,	9·2 ,,
,, ,, ... 1 ,,	9·4 ,,
,, (washed) ... ... 1 ,,	6·0 ,,
Lint (new) ... ... 1 ,,	6·0 ,,
,, ,, ... 1 ,,	7·0 ,,
,, ,, ... 1 ,,	6·6 ,,
Surgical gauze ... ... 4 layers.	14·2 ,,
,, ,, ... 8 ,,	17·6 ,,
,, ,, ... 12 ,,	16·0 ,,

To sum up, it may be concluded that the percentage of ether afforded by a Skinner's mask, adjusted as described, lies ordinarily between 5 and 15 according to the extent of douching and the nature of the fabric employed. Gauze yields a higher percentage than lint or flannel, the percentage rising roughly according to the number of layers. With flannel or with lint, so adjusted that all inspirations and expirations pass through the fabric, a more or less equable atmosphere containing approximately 8 or 9 per cent. of ether vapour may be depended upon. This fact we look upon as the most important feature of our experiments.

Finally, we desire to express our indebtedness to Professor Waller both for the resources of his laboratory and for the ready method of ether (and of chloroform) estimation that has contributed so much to the quantitative study of anæsthetics and of anæsthesia.

ROYAL INSTITUTION.—On Thursday next, Feb. 1st, at 3 o'clock, Professor A. M. Worthington begins a course of two experimentally illustrated lectures at the Royal Institution on the Phenomena of Splashes; and on Saturday, Feb. 3rd, Sir Alexander C. Mackenzie delivers the first of a course of lectures with musical illustrations on (1) Russian Music of To-day (with the kind assistance of the Hans Wessely Quartet); and (2 and 3) Franz Liszt (Centenary). The Friday evening discourse on Feb. 2nd will be delivered by Sir James Mackenzie Davidson on Vital Effects of Radium and Other Rays, and on Feb. 9th by Dr. J. A. Harker on Very High Temperatures.

ALCOHOL INJECTION OF THE GASSERIAN GANGLION FOR TRIGEMINAL NEURALGIA.

BY WILFRED HARRIS, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

DURING the last 3½ years I have seen 90 cases of intractable trigeminal neuralgia, 86 of whom I have treated with alcohol injection; 65 were females and 25 were males. In only three cases was no relief obtained, owing to the nerve not being found; one of these had previously been operated on unsuccessfully for gasserectomy and the scar tissue was so dense that it was impossible to manipulate the needle. In three others slight definite improvement resulted and in the remaining 80 cases complete relief was obtained for intervals varying from as little as two months and four months in two cases to 2½ years and more. For the majority 12 months' complete relief of pain may be looked on as a minimum, if the nerve is definitely hit and anæsthesia produced; while two to three years and more may be expected when the depth of the anæsthesia indicates that the nerve has been properly destroyed by the alcohol.

Several patients have come to me who had previously been unsuccessfully injected with alcohol elsewhere, and I have heard it stated that the treatment was of no use, and also that no anæsthesia is produced by the alcohol injection. That this may be so in the hands of those who have not practised the method thoroughly on the dead body, or who have not the patience to find the nerve before performing the injection in the living patient, I can readily believe. I wish to state most emphatically that such failures in cases of genuine trigeminal neuralgia are due to errors in technique, owing to which the nerve is neither struck nor injected with the drug. Strong alcohol injected into any nerve trunk destroys the nerve fibres almost instantaneously; it is, indeed, a chemical resection of the nerve, and total loss of function of the nerve will ensue until regeneration occurs. It is to prevent this regeneration of nerve fibres that I have adopted the modified technique described below, in order to destroy the nerve cells in the Gasserian ganglion, and thus to render impossible the downgrowth of new nerve fibrils to replace those destroyed by the alcohol.

The great advantage of extirpation of the Gasserian ganglion over Schlösser's method of alcohol injection of the nerve trunks has been the permanence of the cure in the former treatment, as opposed to the temporary relief of a few months to three or more years obtainable by the injection. The severity of the Krause-Hartley operation for extirpation of the Gasserian ganglion, owing to the necessity for a large trephine opening, and considerable pressure being exerted upon the brain during the process of exposing the ganglion, has deterred a large number of sufferers with trigeminal neuralgia from seeking relief by this means.

I have therefore endeavoured to improve on the method of deep alcohol injection of the nerve trunks by carrying the injection of strong alcohol through the foramen ovale into the Gasserian ganglion itself, in order that, by destroying the nerve cells in the ganglion, regeneration of nerve fibres along the degenerated nerve trunks shall be prevented, and thus to substitute permanent cure of the pain for the temporary relief of a few months to a few years which was hitherto obtainable. In this way it appears to me possible to obtain all the advantages of the Krause-Hartley operation without its attendant deformity and dangers, or even the necessity of a general anæsthetic.

In my first paper[1] three years ago on the alcohol injection treatment, I indicated that in practically every case it is possible to pass the needle through the foramen ovale into the Gasserian ganglion, and I had found by experiment on a large number of bodies in the post-mortem room that it was possible to inject the Gasserian ganglion through this foramen, using an alcoholic solution of methylene blue for the purpose, the ganglion being found afterwards stained deeply blue with the dye. I then felt that partial or complete destruction of the ganglion by injection of alcohol into it through the foramen ovale would be the ideal treatment in those cases of neuralgia which involve the third division of the nerve either alone or in conjunction with the second division, which form a majority of the total number of cases of trigeminal neuralgia met with. No recurrence of the pain after such a treatment should ever happen, just as in cases when the Gasserian ganglion has been successfully extirpated.

It is a debatable question whether in those cases of neuralgia limited to the first and second divisions it is better to practise recurrent injections for the two nerve trunks and leave the important area of sensation on the tongue and lower jaw supplied by the third division unimpaired, or whether it would be better in every case to attack the ganglion through the foramen ovale, and thus render the whole area of the trigeminal nerve anæsthetic. That is to say, is it better to suffer the return of the neuralgia at intervals with recurring injection treatment and retain sensation on the tongue and lower jaw, or is it wiser to purchase permanent immunity from pain at the price of permanent loss of sensation on the half of the tongue and lower jaw, in addition to the numbness over the area of the trunks affected by the neuralgia?

During the last 15 months I have injected the ganglion through the foramen ovale with 90 per cent. alcohol in seven patients, one man and six women. At first I attempted this only in thin subjects who had not been injected before, because of the greater ease of manipulation of direction of the needle, and in patients in whom the third division was chiefly involved, but I have now also used it for cases in which the second division alone was affected, and I am inclined to think it will be the sounder course to use the method also in those comparatively uncommon cases in which the paroxysmal neuralgia is limited to the first and second divisions of the nerve. True trigeminal neuralgia affecting the first division alone is very rare; I have had only one case in 90 cases of the disease.

Destruction of the nerve trunks outside the skull, in cases of trigeminal neuralgia—whether by the knife or alcohol injection—is probably always followed, sooner or later, by recurrence of the pain, the intervals of freedom varying from a few months to three or four years, according to the degree to which the nerve has been destroyed. It is true that in many instances injection of alcohol in the neighbourhood of the nerve trunk has been followed by complete relief of the pain for a few weeks or months, even when no trace of anæsthesia has been produced; such perineuritic injections are, however, most unreliable in their effects, as the pain may recur at any moment. To ensure complete freedom from pain for many months it is necessary to inject the alcohol into the nerve trunk, so that lasting anæsthesia shall be produced. The success of the injection can be accurately gauged by the depth of the anæsthesia produced, and if this be done properly, so that there is complete loss of sensation to touch, pin-prick, and to pressure over the larger portion of the area supplied by the nerve, we may then count with tolerable certainty on complete relief of the pain lasting from twelve months to two or three years. I have, indeed, several patients who have had no return of pain whatever for the last two and a half years. Extremely satisfactory though these results are, as the injection can be repeated if the pain returns, yet it is obviously preferable to obtain permanent relief, without having recourse to renewed injections at intervals.

I first injected the Gasserian ganglion with alcohol 13 months ago for a man with typical tic douloureux of the second and third divisions. He still remains perfectly well, with no pain of any kind, and though an equal result so far might have been obtained by injection of the superior and inferior maxillary nerves outside the skull, yet the probability is strong that the immunity from pain in his case will last far longer, if not permanently.

CASE 1.—The patient, aged 43, sent to me at St. Mary's Hospital in November, 1910, by Mr. C. A. Morton, of Bristol, began to suffer from typical tic douloureux in the right cheek and nose two years previously. After suffering for 18 months spasms of gradually increasing severity, the infra-orbital nerve was divided on the cheek by Dr. A. Fells. This gave him relief of all pain for three months, with resultant numbness of the cheek, right upper lip, and side of nose. In July, 1910, similar spasms of pain started in the right lower jaw, the pain darting back into the ear and into the back of the tongue. These spasms of acute pain continued daily in increasing number until his admission to St. Mary's on Nov. 24th. There was then no detectable anæsthesia on the right cheek or upper lip, or elsewhere.

On Nov. 26th I injected the right foramen ovale, using a few drops of 2 per cent. eucaine, followed after a few seconds by 20 minims of 90 per cent. alcohol. The patient said afterwards the injection caused practically no pain at all. There was produced immediately complete anæsthesia of the whole of the right fifth nerve distribution to all forms

[1] Proceedings of the Royal Society of Medicine, Neurological Section, Feb. 25th, 1909, p. 80. See also THE LANCET, May 8th, 1909, p. 1310.

of sensation, touch, pressure, and pin-prick, with loss of the right conjunctival reflex, and also complete loss of taste on the right half of the tongue; the palate unfortunately was not tested. Next day the anæsthesia had diminished considerably on the forehead and cheek, so that a firm touch or pressure was now felt, though there remained complete analgesia to pin-prick (Fig. 1). A week later light touches

FIG. 1.

CASE 1.—Chart of sensation: loss on right fifth nerve area, taken Dec. 31st, 1911, thirteen months after the injection of the ganglion. The dotted area indicates loss of perception of light touches and complete loss of perception of pin-prick, except as a touch or pressure.

were still unperceived on the forehead and cheek, and only firm pressure of the lower lip and chin, though the analgesia remained complete as before.

Now, 13 months later (Dec. 31st), the patient has had no return of pain whatever, and on examination I find he still cannot feel a pin-prick at all on the right fifth nerve area, and also there is very definite loss to light touch, with loss of the conjunctival reflex. The analgesia extends over both upper and lower jaws inside the mouth and includes the right half of the tongue, and the hard palate as far back as its junction with the soft palate. Although at first after the injection there was weakness of the right masseter and pterygoids, this has now completely recovered.

The recovery of the motor paresis of the jaw muscles, in spite of permanent analgesia, is explained by the fact that the motor trophic centre lies in the motor nucleus in the pons, the motor branch of the fifth having no connexion with the Gasserian ganglion. Consequently, an injury to the motor fibres by alcohol injection, even inside the foramen ovale, may be recovered from, whereas the trophic centres for the sensory fibres of all three divisions of the trigeminus are the nerve cells within the ganglion. Destruction of the motor portion of the nerve, and consequent permanent disfigurement from wasting above and below the zygoma, is a constant result of the major operation for excision of the ganglion, owing to a considerable portion of the motor branch being necessarily destroyed with it.

My technique for injecting the Gasserian ganglion varies only in detail from that of injecting the inferior maxillary nerve at the foramen ovale; instead of inserting the needle close below the lower border of the zygoma, I choose a point either on or slightly below the line joining the incisura notch to the ala nasi. This line in the average skull, when the teeth are in position, corresponds to the lower border of the sigmoid notch of the lower jaw. To reach the foramen ovale, therefore, the needle must be directed slightly more upwards, making it thus easier to pass the point through the foramen. As soon as the nerve is reached at the foramen, I inject it with 90 per cent. alcohol, using about 1½ c.c., but if no general anæsthetic is being given I precede the injection of the alcohol by injecting 6 or 7 minims of 2 per cent. eucaine solution into the nerve, thus rendering the subsequent injection of the alcohol comparatively painless. If there is as a result deep anæsthesia of the lower lip and chin, which will certainly develop at once if the nerve itself has been injected, I then feel with the point of the needle for the lips of the foramen ovale, if this has not already been felt. Sometimes the needle slips easily through the foramen, sometimes it has to be worked through, but no degree of force should be used.

In two instances I have found that after feeling the lips of the foramen with the point of the needle injection of the nerve at that point has produced total anæsthesia of the whole fifth nerve, no doubt owing to the alcohol infiltrating the tissue of the ganglion by passing through the root of the third division, as I have seen many times occur in the dead body when injecting the nerve at the foramen ovale. During the injection the patients complained of pain spreading into the cheek and forehead, and in both of them I considered it unnecessary to work the needle through the foramen into the ganglion, but in both the depth of the anæsthesia on the first and second divisions faded away after 10 or 15 minutes, so that tactile sensations began to be perceived on the forehead and cheek, and on the following day tactile sensation on these areas was practically normal again, though pin-prick was perceived only as a touch.

If the tic douloureux is affecting the third division alone, and this is the commonest variety in my experience, the inferior dental being by far the most frequently involved, such a result is, I think, the ideal to be aimed for, but if the second division is also affected by the pain, as in the upper gum, cheek, or nose, then more of the ganglion must be destroyed, and the needle must be worked through the foramen into the substance of the ganglion to the depth of another quarter of an inch. A drop or two of the alcohol is then cautiously injected, considerable resistance to the push of the piston being experienced if the point of the needle remains within the nerve tissue. Another 1–1½ c.c. of alcohol should then be injected, a few drops only at a time, at intervals of not less than two minutes, meanwhile testing the sensation on the cheek and forehead with a blunt pin. When neither the pressure of the head of the pin or a sharp prick on the forehead is any longer perceived at all, enough has probably been done, and the needle should be slowly withdrawn. Even now the depth of anæsthesia will probably fade away after half an hour or so, so that on the following day deep anæsthesia and loss of taste may persist on the palate, and complete loss to pin-prick and even to pressure on the upper lip and lowest part of the cheek, yet tactile sensation may be fair on the forehead and below the eye, with a normal conjunctival reflex. When this is the case there is no danger of any keratitis supervening, such as may occur when total anæsthesia of the eyeball persists after complete destruction of the ganglion.

Sometimes, after pushing the needle through the foramen ovale, the point of the needle may leave the nerve tissue and enter the cave of Meckel, and cerebro-spinal fluid may drip from the needle. If the injection of alcohol be then commenced no resistance will be felt to the push of the piston, and instantly the patient will complain of severe headache at the base of the skull and back of the head. Should this occur the needle must be partially withdrawn, and then worked through the posterior edge of the foramen, so as to keep the point within the substance of the ganglion.

Another result of this slight error in direction that may occur is that the point of the needle may pass in front of the ganglion and strike the root of the second division of the nerve before it enters the foramen rotundum. This is recognised by the patient's sudden complaint of pain in the nose and cheek, and if the nerve be injected here, deep anæsthesia on the hard palate and sometimes on the front of the soft palate, together with total loss of taste on this area will be produced, in addition to the anæsthesia of the upper jaw, nose, cheek, and upper lip which would result from injection of the nerve by the ordinary route in the sphenomaxillary fossa. This has happened to me in two cases, in both of whom deep anæsthesia and complete loss of taste on half the palate were produced, together with complete analgesia on the upper lip and lower part of the nose, the analgesia becoming slighter below the eye, not sufficient alcohol having been injected to destroy the whole nerve completely.

More often than not injection of the second division in front of the foramen rotundum by the ordinary route produces little or no anæsthesia on the palate, though there may be deep anæsthesia as a result on the jaw, nose, and cheek; this is no doubt due to the nerve trunk being struck in front of the branch to Meckel's ganglion. Another branch which I have never found anæsthetic after injection at this point is the temporo-malar, the anæsthesia always ending sharply at the outer canthus of the eye. Whether this is due to the usual area assigned to the temporo-malar branch receiving alternative supply from the auriculo-temporal or supraorbital nerves, or whether it is due to the temporo-malar branch originating far back from its main trunk, almost at its exit from the foramen rotundum, I am uncertain.

Injection for the second division at the foramen rotundum is usually more difficult than for the third division at the foramen ovale, and in a certain proportion of cases it is

impossible. There is also more likelihood of hæmatoma from wounding the internal maxillary vessels.

These points are additional reasons for my preference for injection of the Gasserian ganglion through the foramen ovale.

CASE 2.—In one patient, a lady 86 years of age, who had suffered from tic douloureux of the second division chiefly, and to a less degree of the third division on the right side for the past eight years, I injected the right Gasserian ganglion two months ago under chloroform. Using the method I have described, I was able to feel the lips of the foramen ovale with the point of the needle, although the patient was unable, of course, to give me the indication of feeling an electric twinge down into the lower lip and chin. I injected only 1½ c.c. of 90 per cent. alcohol without any eucaine, but after the patient came round from the anæsthetic complete anæsthesia on all three divisions was present, with loss of taste as well as loss to pin-prick on the right half of the tongue. There has been no recurrence of pain whatever since, though she complained of a "wooden" feeling of the whole of the right side of the face.

CASE 3.—In another patient, a lady aged 41, I injected the left Gasserian ganglion twice in October last, with ten days' interval, using 2 c.c. of 90 per cent. alcohol on each occasion. She had suffered from severe tic douloureux of the left second and third divisions for five years. Two years before she came to me she had obtained relief from a course of numerous injections of alcohol, for which she was put under general anæsthesia six different times. As a result of that treatment she had diplopia which lasted nearly three months, and paralysis of the pupil, though the pain was completely relieved for 19 months, when in July last it returned furiously.

When I saw the patient there was no trace of anæsthesia remaining, though she says she was quite anæsthetic on both lips and jaws on the left side after the treatment. The left pupil was typically Argyll-Robertson in character, there being no trace of reaction to light, but a slow full reaction to accommodation. This is doubtless due to the alcohol two years ago having infiltrated the nerve branch to the inferior oblique, during the process of injection of the second division in the spheno-maxillary fossa.

On Oct. 16th last I injected the third division in this patient, local anæsthesia only of ethyl chloride spray and eucaine being used. Using the method I have already described above, I injected the nerve at the foramen ovale, and also the Gasserian ganglion, using altogether 2 c.c. of 90 per cent. alcohol. The immediate result was complete anæsthesia on the lower lip and tongue and the rest of the third division, with complete loss of taste on the front of the tongue on that side, with deep analgesia and loss of light touch over the remainder of the fifth nerve supplied by the second and first divisions. Although the conjunctival reflex was partially lost no keratitis followed, but pain of a darting character still troubled her in the lower jaw and cheek and also in the temple, where she had not had it before.

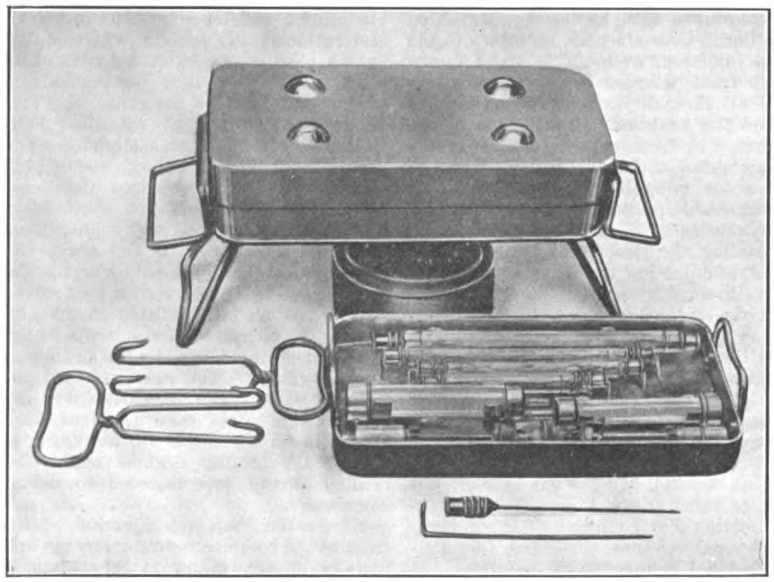
Ten days later I therefore injected again into the Gasserian ganglion through the left foramen ovale, passing the needle to a depth of just 2 inches. I used no eucaine this time, but injected 2 c.c. of 90 per cent. alcohol slowly into the ganglion. When finishing the injection she became somewhat faint and retched a little, and she was kept in bed for the next two days, slight giddiness and retching continuing for that time. Total anæsthesia to all forms of sensation, touch, pin-prick, and pressure was immediately produced over the whole area of the fifth nerve, including the eyeball, auditory meatus, and to a less extent the membrana tympani. There was complete loss of taste on the front of the tongue on that side, as before, and now also loss of taste on the left half of the front of the palate (Fig. 2).

During the next fortnight she complained of darting neuralgic pains in the left cheek and temple, which gradually diminished and then disappeared entirely, the anæsthesia remaining as intense as before. Keratitis developed in the anæsthetic eye on the fifteenth day after the second injection, necessitating sewing together of the lids for a time, but she is completely cured of her neuralgia, and I think is likely to remain so permanently.

FIG. 2.

CASE 3.—Chart showing area of anæsthesia after the second injection of the left Gasserian ganglion on Oct. 26th. The shaded area indicates loss to touch, pin-prick, and to firm pressure. The kidney-shaped area above the left eye indicates an area of skin which showed no anæsthesia at all after the first injection on Oct. 16th, but became completely anæsthetic after the second injection. The dotted area indicates loss to pin-prick, with only slight tactile diminution, her comb not being felt properly, and pin-prick perceived only as touch.

FIG. 3.



Injection outfit consisting of steriliser 6 in. by 3 in., fitted with cover, reversible to form tray; perforated tray fitting into steriliser or cover, containing flat metal plate with clips to hold eight needles in cases, and two syringes. The syringes and needles required are taken out and placed in the tray for boiling in weak soda solution. In front is seen a 2½ in. needle, 1·25 mm. calibre, with stilet.

On another occasion I should not attempt such rapid or complete destruction of the ganglion owing to the faintness produced and the risk of keratitis, but if the injection is made slowly, only a few drops being pushed in at a time at intervals of two minutes, the depth of the anæsthesia can be graduated almost to a nicety and no unpleasant symptoms whatever will result.

If a general anæsthetic is used, and some patients insist upon it, chloroform is usually the most suitable, and it should be given lightly, and as soon as the needle reaches the nerve there will probably then be strong reflex contraction of the facial muscles on that side, as though pain were felt, though afterwards there is no recollection of feeling anything. In my first paper in 1909 I described this sign as a definite indication that the nerve is reached, but experience has since taught me that it is not an infallible sign, and equal reflex screwing up of the face may occur when the nerve has not been reached.

If, under an anæsthetic, the lips of the foramen are felt by the point of the needle, or from other indications it is assumed that the point of the needle is within the nerve, the anæsthetic should be discontinued, and the injection of the alcohol begun slowly, a few drops at a time. As consciousness commences to return it will be found that a smart prick upon the chin or lower lip evokes no reflex movement at all, if the alcohol has been placed correctly within the nerve, owing to the anæsthesia of the skin immediately induced, while a pin-prick upon the other side of the chin or lip will provoke strong reflex movement and signs of displeasure, long before the patient is sufficiently conscious to answer questions. Should, therefore, the reflex contractions of the face be equally brisk on the two sides, a little more anæsthetic may be administered, and a fresh attempt then made to find the foramen and then to inject the nerve.

I have thus in several patients been able to inject the third

division at the foramen ovale under chloroform successfully in whom I had previously been unable to find the nerve owing either to their inability to keep still or else to the fact that patients do not always complain of a twinge of pain along the whole distribution of the nerve's supply, and thus the needle may have been correctly placed and then partially withdrawn and tried in a different direction owing to the failure of the patient to give the expected signal when the nerve was hit. That this undoubtedly does occur sometimes I have had definite proof in three patients when injecting the infra-orbital nerve at the infra-orbital foramen. All three denied feeling any pain in the upper lip or nose when the needle was inserted into the infra-orbital foramen, and the injection was completed, in each case producing deep anæsthesia of the whole distribution of the nerve without any pain being felt at all in the upper lip, although this part became as deeply anæsthetic as the rest.

To get good results it is necessary to have suitable tools to work with, and it may be of value to others who wish to try this treatment to know what type of needles and syringe I use. Messrs. Maw and Sons have supplied to my designs an outfit (Fig. 3) consisting of a 6 in. by 3 in. steriliser with perforated tray, and a cover with handles, into which the tray also fits. Into the tray slips a flat metal plate on which are arranged in spring clips four split-tube needle-holders, each containing two needles, and two Record syringes with their pistons separately. The syringes are of 2 c.c. and 20 minims capacity, to be used for 90 per cent. alcohol and 2 per cent. eucaine solution respectively. The needles are of drawn steel, nickelled, with a short sharp point bevelled at an angle of 20°, and long mounts roughened by coarse milling to give a good grip to the fingers, and brass-wire stilets to fit the bore. Besides two strong hypodermic needles there are one 35 mm. long and 0·6 mm. bore, and another 50 mm. long and 0·9 mm. bore, both useful for injecting the infra-orbital foramen in thin- or fat-cheeked people; two 2½ in. long and 1·25 mm. and 1·1 mm. bore respectively, and two longer and stouter needles, 3 in. and 3½ in. in length and 1·25 mm. and 1·4 mm. bore. The 2½ in. needles I use for injecting the foramen ovale, and in thin subjects also for the foramen rotundum, while the longer needles may be used for the foramen rotundum in larger and stouter subjects. All these needles, except the three smallest, may also be used for lumbar puncture in children and adults, for which they are extremely suitable.

Wimpole-street, W.

THE SURGICAL TREATMENT OF STERILITY IN WOMEN.[1]

BY FREDERICK J. McCANN, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO IN-PATIENTS, SAMARITAN FREE HOSPITAL FOR WOMEN, MARYLEBONE-ROAD, LONDON, N.W.

IN appraising the value of treatment for such a complex condition as female sterility there must ever be present to the mind the necessity for distinguishing between a coincidence and a consequence. This is the more necessary when we consider how little real knowledge we possess regarding the subtle changes which promote or hinder the occurrence of conception in the human female. Anatomical or pathological alterations in structure forming definite barriers to conception are easy to understand, but the more minute changes which underlie the occurrence of conception in many instances still remain a sealed book. It is, however, to the treatment of some of these anatomical and pathological changes in the female genitalia that I desire to direct attention in order to show what surgery can do to promote a cure.

It must be laid down as a fundamental law that no female should be subjected to prolonged and painful treatment or to any surgical operation for the cure of sterility unless it is proved that the male is potent as regards coition and fertility. By way of illustration let me recall two recent examples.

A woman, aged 38 years, came to consult me because she had missed a menstrual period and because her abdomen was enlarging. She had been married 15 years and fancied she was pregnant. I found on examination that she was a *virgo intacta*, and on putting a few judicious questions I ascertained that connexion had never really taken place. Further investigation proved that her husband was impotent.

The second example was that of a woman, aged 36 years, who had been married for ten years and was anxious to have a child, if only for succession reasons. Her husband was ten years her senior and she had had treatment of various kinds and had, of course, been curetted. After a careful pelvic examination of her internal organs no cause could be detected to explain her sterility. I sent her husband to a surgical colleague in order to have his spermatic fluid examined, and it was then found that he had azoöspermia.

These two cases will serve to emphasise the importance of male sterility, a condition which is far from uncommon and which probably accounts for about one-fourth of the cases. So much attention has been directed in the past to the treatment of uterine flexions, fancied or real strictures of the cervical canal and its orifice, and to scraping the uterine cavity, that the ovaries and tubes seem to have been entirely forgotten. Such methods of treatment have proved disappointing to the patients and have brought discredit to the practitioner and his calling. Yet the condition of the tubes and ovaries is one of the most important factors in the reproductive process. How often do we see treatment directed to scraping or attempting to cause enlargement of an undersized uterus, forgetting all the while that the ovaries and tubes may be, and probably are, atrophic, and no treatment directed to the uterus is likely to be beneficial. Quite recently I saw a woman with an undersized flexed uterus who came for treatment because of her sterility and who had been curetted two years previously.

One of the most common causes of sterility in both sexes is gonorrhœa, and in the female it is the results produced in the tubes and ovaries through gonorrhœal infection which so often lead to permanent sterility. Infection post abortum and post partum may lead to a similar result or infection the result of appendicitis, whilst tubercle may also be a cause. Such infections produce adhesions of the ovaries and tubes to the back and side wall of the pelvis, to the rectum, to the uterus, or to one another, or the Fallopian tubes become thickened and their abdominal ends closed. Improvement under appropriate treatment may result, but with gonococcal infection the results tend to persist, the outstanding features of this infection when attacking the Fallopian tubes and pelvic peritoneum being its chronicity and its tendency to form adhesions.

Cure of Sterility by Double Salpingostomy.

It was not until 1907 that I had an opportunity of proving what could be done for the sterile woman with sealed tubes.

A patient, aged 28 years, was sent to me on account of her sterility. She had been married two years, and since her marriage had had excessive bleeding at her menstrual periods which lasted 14 days. Menstruation previous to marriage had been regular, painless, lasting seven days, and of moderate quantity. She complained of pelvic pain at intervals, slight sickness, and abdominal distension. The uterus was found to be displaced backwards partially fixed through adherent appendages, and the Fallopian tubes were thickened. An investigation into the condition of her husband was made, when it was found that he had had chronic gonorrhœa, which was now cured. I explained what I intended to do to the patient and her husband, and with their consent I operated. The abdomen was opened in the middle line by a sub-umbilical incision, and both Fallopian tubes were found to be adherent, thickened, and completely sealed at their abdominal extremities, each tube terminating in a club-shaped swelling. The ovaries, which were slightly adherent, appeared to be of normal size and structure. One Fallopian tube was brought out through the incision and surrounded with a gauze sponge. An incision was then made along the dorsal aspect of the tube towards the club-shaped extremity for a distance of one inch, thus opening up the abdominal end of the tube. The remains of the fimbriæ could be recognised as having been inverted into the lumen. The tubal mucosa was then united to the serous covering of the tube with fine catgut inserted on a curved intestinal needle, thus accurately uniting the edges and stopping all bleeding. The opposite tube was then brought up and treated in a similar manner. The uterus was suspended by intra-peritoneal fixation of the round ligaments, a silkworm gut suture being passed on each side through the fascia of the abdominal wall, muscle, peritoneum, and under the

[1] A paper read before the Harveian Society of London.

uterine end of the round ligament, and then through peritoneum, muscle, and fascia, to be tied and cut short outside the fascia. The omentum was then pulled down and placed behind the uterus, whilst the appendages were placed on its anterior surface, the uterine suspension and the arrangement of the omentum being for the purpose of preventing the further development of adhesions. The patient made a smooth recovery. Three months later I was gratified to hear that she was pregnant, and ultimately she was safely delivered of a large male child. Her medical attendant wrote to say: "Except that the head stuck at the outlet requiring forceps and anæsthetic just at the end there was nothing remarkable or unusual in the labour."

The Operation of Salpingostomy and its Technique.

The operation of making a new abdominal opening for the Fallopian tube is termed salpingostomy, and was first attempted by Skutsch in 1889.[2] He excised a small oval portion from the lateral wall of the bulbous extremity of the Fallopian tube and then sutured the mucosa to the peritoneal coat. A. Martin[3] removed the end of the tube, uniting the mucosa to the serosa by sutures. Out of 63 operations conceptions followed twice. Mackenrodt also records two successes in 13 cases.

The comparatively small number of successes following these operations led me to conclude that improvements in the technique might produce better results. The removal of the extremity of the tube as recommended by Martin, followed by subsequent suture, is much more likely to be followed by contraction and closure of the opening, whereas a free incision along the upper surface of the tube has the advantage that contraction of the circular muscular fibres in the tube wall will tend to maintain its patency. Further, it is necessary to use fine catgut, which will be quickly absorbed, and also to make sure that all bleeding is arrested. All these operations must be done with the utmost gentleness and any adhesions snipped with scissors, for if they are torn by the hand introduced into the pelvis the tube may share the same fate and be irreparably damaged. For this purpose a large abdominal incision is necessary so that all adhesions may be seen and separated under visual control.

The termination of the operation by suspending the uterus is necessary in order to prevent a recurrence of the adhesions. That this is so I have proved through operating a second time on a woman who had undergone the operation of salpingostomy, but had not had the uterus suspended. At the first operation there were numerous adhesions surrounding the appendages, and both tubes were occluded at their abdominal ends, the uterus itself being inclined backwards. For some time after the first operation the patient had felt relief, but later her backache returned, and on examination I found that the uterus had again became adherent. A second operation was therefore performed and the adhesion separated. When the tubes were inspected both abdominal ends were found to have remained patent. The uterus was suspended by the round ligaments and all the symptoms have been relieved. The patient has not become pregnant, but 12 months only have elapsed since the second operation. I have, however, satisfied myself that the tubes do remain patent, and, further, that it is necessary to combine a suspension operation with salpingostomy.

The operation of salpingostomy should always be done by the abdominal route in order that a thorough inspection of the pelvic contents may be made. Passing a probe down the tube is, I believe, an error. If the tube is found to be patent then the passage of a probe is unnecessary, whilst if it is not patent harm may be done by creating a false passage. We know, too, that pregnancy has occurred even after ligature of the Fallopian tubes, so that Dame Nature will help us if we do not do too much local injury.

The time element is important, for I have repeatedly noticed that in the more chronic cases of pelvic adhesions from tubal disease the ovaries were small, suggesting the existence of an atrophic process. If this be substantiated it is surely an important argument against delay in advising operative treatment when indicated. For it need hardly be added that the capability of the ovary to produce ova is as essential as the patency of the Fallopian tube.

It has been argued that restoration of the patency of the abdominal tubal ostia might lead to a fresh infection from the tubes, but in the majority of chronic cases active infection has long since disappeared, and the contents of the tubes, if there be any, are found after bacteriological tests to be sterile. If the tube contains any fluid this should be expressed. Much, however, depends on the proper selection of cases, for if this operation were adopted in all stages of tubal disease without selection it would soon be discredited.

Cases Suitable for the Operation.

Let us see what cases are suitable and how they can be recognised. In the first place, it is assumed that the condition of the husband has been investigated, and if he has chronic gonorrhœa this should be treated. Besides the history of sterility the woman will complain of increased loss at the monthly periods, with or without some premenstrual pain. There may be, as in one of the cases narrated, some complaint of sickness and abdominal distension, indicating involvement of the peritoneum. There is frequently backache referred to the sacrum when the uterus is fixed backwards, and coitus may be painful. On examination the uterus is found to be partially fixed—i.e., it can be moved, although it cannot be replaced in its normal position. It may be tender on pressure, and the Fallopian tubes are found to be thickened and larger than normal. But the uterus may exceptionally be freely moveable, although the tubes are sealed. This I have proved by actual inspection through an abdominal incision. On the other hand, the adhesions may be so extensive that the uterus is fixed backwards in the pelvis. Even in such cases the tubal ostia may have remained patent although surrounded by adhesions. Under such circumstances it suffices to divide the adhesions, to arrest all bleeding, and to suspend the uterus in the manner indicated. Successful pregnancy has frequently followed such operations in my own practice.

A good illustration was afforded by a patient upon whom I operated for an early pregnancy in the left tube. Her husband confessed to me that he had infected his wife with gonorrhœa and in consequence she developed salpingitis. A tubal pregnancy was diagnosed necessitating an abdominal operation. The appendages on the left side were removed, and on inspecting the right tube and ovary they were found to be embedded in adhesions. The adhesions were carefully divided, and it was found that the abdominal end of the tube was still patent. The patient made a good recovery from the operation, and 18 months later gave birth to a full-time, healthy male child. This was a source of great gratification to both parents, but especially to the husband, who was deeply grieved over the injury he had inflicted on his wife.

Case of Tubal Pregnancy following Salpingostomy.

As far as I have been able to ascertain from a search through the literature no example of the occurrence of tubal pregnancy after the operation of salpingostomy has been recorded.

On June 28th, 1910, I operated on a woman who had an adherent retroverted uterus, and at the operation the abdominal ends of both tubes were found to be sealed. The adhesions were divided and a new opening made for each tube. The uterus was then suspended in the usual manner. The patient made a good recovery and left the hospital at the end of three weeks. Soon after her return home she must have been impregnated, for early in September during my absence on a holiday she was admitted into another hospital, and an early ruptured tubal pregnancy was removed.

This case is one of great interest and importance, but it does not warrant the conclusion that the operation of salpingostomy renders a woman more liable to the occurrence of tubal pregnancy. It shows, however, that the tube remained patent after the operation.

A Test Case.

Let me now recite to you what may fairly be claimed to be a test case.

A patient, aged 30 years, married for six years and sterile, came to consult me on account of great pain at her monthly periods, the passage of membranous casts, and her continued sterility. Menstruation had begun when she was 17 years of age, and was regular and somewhat profuse. Six months

[2] Verhandlungen der Deutschen Gesellschaft für Geburtshülfe und Gynäkologie, 1889, Band iii., p. 376.
[3] Sammlung Klinischer Vorträge, Nr. 343; Verhandlungen der Deutschen Gesellschaft für Gynäkologie, IV. Kongress, p. 245; Krankheiten der Eileiter, p. 215.

after her marriage she stated that she had had a more or less constant loss of blood for three months, and then membranous casts were passed. Menstruation then recurred every five weeks, lasting three days without profuse loss. Pain in both iliac regions was experienced for one week before the onset of the period, and it continued during the period. Backache continued in the intervals. The patient had been curetted two years previously without benefit, had seen specialists in this country, in France, and in America, and had undergone treatment by electricity and other methods.

I found on examination that the uterus was displaced backwards and partially fixed, and there was evidence of tubal thickening. Both husband and wife were very anxious to have a child. I therefore recommended an exploratory operation, which was performed in October, 1908. The appendages were adherent, with their abdominal ostia sealed. The adhesions were divided, a new opening was made in each tube, and the uterus was suspended. She made a good recovery and again reported herself on March 8th, 1909, when it was noted that the pre-menstrual pain was better and also the backache. She still passed casts at her period, accompanied by pain. The uterus was found to be in good position. On July 15th, 1910, the patient again came to see me as she was contemplating going abroad with her husband. She looked and felt much better and had lost her headaches from which she previously suffered, but she still passed membranes. I had an opportunity of examining one of the membranes and it was not so thick as those I have examined in bad cases of membranous dysmenorrhœa. I gave her iodide of potassium and told her to take it with great regularity. She returned from abroad and came to see me on Jan. 2nd, 1911. She then stated that menstruation had ceased on Sept. 28th, 1910, and that no cast was passed during that period. The breasts were swelling and she had morning sickness. On examination I found that she was three months pregnant. She had taken the iodide of potassium from July 15th, 1910, to Oct. 8th, 1910. On July 15th, 1911, she gave birth to a well-developed male child.

Here, then, was an operation performed in October, 1908, followed by the occurrence of conception two years later, showing clearly that the patency of the tubes had been maintained. Moreover, various methods of treatment had been tried and found wanting until an abdominal section was performed and the cause of the sterility discovered and remedied.

It would appear that the benefit to be derived from such operations becomes apparent within two years, whilst after that interval of time the prognosis becomes correspondingly bad.

I believe this operation of salpingostomy has a great future and deserves to be reckoned one of the triumphs of modern abdominal surgery. If cases are suitably selected according to the indications already mentioned and the potency of the male determined, there is every reason to hope that it will prove of lasting benefit to the previously sterile woman.

It may be said that an abdominal operation, with all its risks, is a severe remedy to recommend. But the risk in the hands of those accustomed to such operations is a small one, amounting, indeed, only to that of the anæsthetic, and for this reason it is not more dangerous than the too frequently performed operation of curetting. Maternity is one of the strongest human instincts, and if the situation is properly explained to both husband and wife consent is not difficult to obtain. No surgeon can promise a successful result, but he can by surgical operation place a woman in such a condition that pregnancy is possible, whereas as long as her tubes remain sealed she is sterile for all time.

Uterine Displacements.

Much has been written for and against the influence exercised by uterine displacements in the causation of sterility. Statistics have been produced to show how backward displacements hinder conception, and again to show that conception is not hindered. But in this regard each individual is a law unto herself, and it is easy to produce statistical evidence to favour either view.

Now that surgical treatment is so frequently employed for uterine displacements, it is beginning to be realised that they do play an important rôle in hindering conception. How this effect is produced is probably owing to the changes resulting in the displaced organs, principally from chronic venous congestion which is evidenced clinically by menstrual pain, increased menstrual loss, and intermenstrual discharge. Here, again, the curette is freely used for the treatment of such conditions, but surely it is illogical to use a curette when the pathological changes are the result of the abnormal position.

That pregnancy so frequently follows after operations undertaken for the cure of displacements is important evidence in favour of the view that in certain individuals they do hinder conception. Let me give two examples.

A patient married for 12 years had one child a year and a half after her marriage and was not again pregnant. She came complaining of bearing-down pain, backache, increased menstruation, and intermenstrual discharge, and could not understand why she did not again become pregnant. On pelvic examination the uterus was found to be slightly enlarged, moveable, and displaced backwards. The patient had had much local treatment without benefit. I recommended and performed ventro-suspension in May, 1909. She was greatly relieved by the operation, and on August 1st, 1910, menstruation ceased, and she found that she was pregnant. The pregnancy proceeded normally and she was finally safely delivered of a female child.

A second example is that of a patient who had had a son a year after her marriage and had not again become pregnant for five years. I was asked to see her because of bearing-down pain and difficulty in standing and walking and because she did not have another child. I found that the uterus was sinking down in the pelvis—descensus uteri—and accordingly recommended hysteropexy. This operation was performed, and within a year she became pregnant and ultimately gave birth to a male child. Both parents had been particularly anxious to have another child.

It would be easy to multiply examples, for there is no doubt that displacements do hinder conception in certain individuals.

I do not employ what is called the Alexander-Adams operation, which consists in shortening the round ligaments after opening the inguinal canal on each side, because I prefer to open the abdomen, inspect the pelvic contents, and deal with whatever may be found. If the tubes are sealed, then salpingostomy is also performed. As pessaries do not cure chronic displacements they should not be recommended. When a backward displacement is adherent pessary treatment is contra-indicated, and operation consisting in the division of adhesions and ventro-suspension is frequently followed by successful pregnancy.

Curetting in the Treatment of Sterility.

A sterile woman still clinging to the hope of maternity, going hither and thither for treatment, will sooner or later be curetted. And yet with increasing experience I am convinced that this operation has definitely limited indications as a method of treatment. Nay, more, I believe it to be in not a few instances distinctly harmful. In the treatment of primary sterility it is rarely indicated; in the acquired form it has a limited sphere of usefulness. All are familiar with the association of spasmodic dysmenorrhœa and sterility: you relieve the dysmenorrhœa and pregnancy follows. For this purpose dilatation of the cervical canal is required, not curetting. Indeed, in a few instances, especially where menstruation is scanty, complete cessation of the menstrual flow has occurred after curetting. Again, after vigorous curetting partial and complete obliteration of the uterine cavity has supervened. Although the curetting may not produce these results, yet it is unnecessary and should not be done. It is indicated in cases of what is termed chronic glandular hypertrophic endometritis associated with free menstrual loss occurring in a uterus normally placed and where no tubal disease exists. Pregnancy may follow curetting for this condition and such cases are well known. Before, however, any scraping operation is undertaken a careful bimanual examination should be made under an anæsthetic in order to exclude the possibility of the existence of tubal disease.

In the acquired forms of sterility curetting is only indicated when the uterus is normal in position, when the appendages are free from disease, and when free menstrual and intermenstrual discharge point to some morbid condition of the endometrium.

A good illustration was furnished by a patient aged

32 years, who had had one child six years previously, and who for succession reasons was anxious to have another. The uterus was slightly enlarged, normal in position, and moveable. No tubal disease could be detected. She was losing freely at her periods, and had a mucoid intermenstrual discharge. The uterus was dilated and lightly curetted, and ten months after the operation she became pregnant and was later delivered of a male child.

Thus in the great majority of cases of primary sterility curetting is an unnecessary operation, and in the acquired forms its indications are limited.

Division of the Cervix.

A few words must be said about what has figured so largely in the past in the treatment of sterility—viz., the operations for division of the cervix. Although it is obvious that as long as the cervical canal is patent spermatozoa may pass through, it is alleged that cervical stenosis does hinder their upward course, as for some time after cohabitation they may be found in the cervical secretion in such cases. The contraction may be at the external os, at the internal os, or in the canal.

The late Sir J. Y. Simpson made a great reputation through his operation of bilateral division of the cervix for the cure of sterility, and undoubtedly he was successful in many cases. Now, if this operation be considered in the light of modern experience it really fulfils many indications. It causes wide dilatation, it cures dysmenorrhœa even when simple dilatation fails, it provides free drainage, and so may lead to improvement in the condition of the endometrium. Simpson used what is called a metrotome or hysterotome (a sort of concealed bistoury), introducing it as far as the internal os, and then withdrawing the instrument pressed out the blade and cut through the cervix on one side in such a way that at first only the internal fibres are divided, and the incision as it becomes lower becomes always deeper till the point emerges somewhat below where the mucous membrane of the vagina becomes reflected on the cervix, while below this point the portio vaginalis is divided in all its thickness. The instrument is then turned round and a similar incision is made on the other side. The wound was subsequently dilated by sponge tents, metal dilators, or the finger is inserted every two or three days for a time, or the corners of the wound are touched with silver nitrate. He speaks of hæmorrhage, cellulitis, and peritonitis as rare complications.

Those who have followed Simpson do not appear to have carried out his idea, for in his operation there is a very complete bilateral division of the cervical tissues. After such an operation there may be discharge and eversion of the mucosa, and in order to obviate these disagreeable sequelæ I have been in the habit of covering the cut surface of the cervix on each side by means of a flap of mucous membrane obtained by under-cutting. Following the division of the cervix a flap is marked out and dissected up; a piece is then excised from the cut surface of the cervix and the flap is stitched to the mucosa of the cervical canal. For the division of the cervical canal higher up I use a small scalpel. A piece of gauze is then placed in the canal and left for 48 hours.

There are examples of spasmodic dysmenorrhœa and sterility which dilatation alone does not cure, and for these such an operation as this should be tried. Much ingenuity has been spent over devising operations for division of the cervix, but Simpson's operation is the most thorough, and with the modification which I have ventured to suggest it has a definite sphere of usefulness.

Time will not permit me to describe other operations, such as ovarian resections, ovarian grafting, and myomectomy, from all of which occasional good results have been obtained. I trust, however, that I have been able to do something towards lifting the veil of quackery and humbug which surrounds the treatment of "sterility in women."

Wimpole-street, W.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—The introductory course in chemistry, physics, and biology for medical students held at University College will begin on Friday, March 1st, instead of, as hitherto, at the beginning of the third term in May. Full particulars may be obtained from the secretary of University College.

THE KLEBS-LÖFFLER BACILLUS.

A FEW NOTES TO EMPHASISE THE IMPORTANCE OF BACTERIOLOGICAL INVESTIGATION.

BY IDA C. TENGELY, M.D. LOND.,
SENIOR ASSISTANT RESIDENT MEDICAL OFFICER, BRADFORD UNION HOSPITAL.

An ulcer of the leg infected with the Klebs-Löffler bacillus.—This occurred in a single woman, aged 33, who had a very large dirty ulcer on the lower half of the left leg. She stated that she had had it for 15 years, and that it had not been healed for 10 years. The left femoral and inguinal glands were enlarged. There were no scars from other ulcers to be seen. Her teeth had been extracted, and no evidence of syphilis could be found. The veins of the leg were not dilated or varicose. There was no history of injury. The patient's general condition was good. There was nothing characteristic about the appearance of the ulcer. For 11 months it was treated in hospital. The treatment included skin-grafting of the ulcer (the grafts took at first and spread, and then for no obvious reason broke down); and at different times the patient was put on potassium iodide, calcium iodide, sarsaparilla, and she was finally given 4½ grains of salvarsan intravenously. This, by the way, caused no unpleasant symptoms. It was thought that after the salvarsan the edges of the ulcer looked bluer and more healthy, but the patient then took her discharge from hospital. She was readmitted in a month prepared to have her leg off. The ulcer was larger and dirtier than ever, discharging pus profusely. At the end of three weeks a swab was taken, and from this was grown a pure culture of the Klebs-Löffler bacillus. The patient was treated with anti-diphtheria serum, two doses of 6000 units and one of 2000 units being given subcutaneously, and the ulcer was treated directly with the serum. This was done by painting it daily with the serum and letting the latter soak in for a minute or two, and then a piece of sterile gauze was stretched over and this soaked with serum. It immediately began to heal and is now quite healed. But it required careful attention owing to the repeated profuse formation of crusts, which had to be continually removed, and which no doubt harboured the bacilli. Also little blebs with blood-stained serum would arise beyond the edges. These were opened and soaked with serum.

Throughout there was no rise of temperature, and the patient appeared to be in the best of health. A swab from the throat was negative, and there was no discharge from ears or nose. The source of the infection could not be traced. The fact that the skin-grafts, after they had taken and were spreading, suddenly broke down suggests that the infection took place then.

The Klebs-Löffler bacillus in aural discharges.—In three cases of discharging ears Klebs-Löffler bacilli were reported to be present in cultures taken from swabs of the discharge. In all three cases the discharge had only been noticed a few days, and did not follow any of the infectious fevers. It was very offensive and in two cases was blood-stained at first. The children had not sore-throats, there was no rise of temperature, and they did not appear to be ill. The cases did not respond well to serum treatment, and the discharge becoming chronic two cases were operated on.

The Klebs-Löffler bacillus in discharge from the eye.—During an epidemic of diphtheria the Klebs-Löffler bacillus was found in cultures taken from the conjunctiva in several cases. In the majority of the affected eyes there was copious purulent blood-stained discharge, but in others there appeared to be a simple conjunctivitis. It was impossible to distinguish these cases as diphtheria without the aid of the microscope. Several of the cases were children who were convalescent from measles.

The Klebs-Löffler bacillus in the throat.—There is no doubt that the diphtheria bacillus (Klebs-Löffler bacillus) can be present in the throat without giving rise to symptoms, as in contact cases; and it is equally true that it can be present in the throat, causing a very mild inflammation without ulceration, without rise of temperature or very slight rise of temperature, and without making the patient very ill. The glands below the angle of the jaw are generally enlarged, but this is not an infallible sign. During the epidemic

already referred to several such cases of sore-throat occurred in which Klebs-Löffler bacilli were present in the throat, and even in pure culture without symptoms or with very mild symptoms. In all these cases as soon as the child complained of sore-throat a swab was taken, a dose of serum injected, and the throat treated with hydrogen peroxide, 1 in 6, so possibly further progress was prevented, but in several it was some weeks before the throat was free from the bacillus and the report on the swab returned negative.

During the epidemic severe cases of clinically typical diphtheria occurred with the mild ones, and the cultures were examined by the City Bacteriologist. In the October number, 1911, of the *Journal of Clinical Research* is recorded a case of primary diphtheria of the external urinary meatus, and in this case it may be noted that there were no marked constitutional symptoms.

Bradford.

NOTE ON

AN INVESTIGATION INTO ULCERATING GRANULOMA OF THE PUDENDA, AS FOUND IN THE GOVERNMENT LOCK HOSPITALS, WESTERN AUSTRALIA.

BY DONALD STEEL, M.B., CH.B. GLASG.,

LATE PATHOLOGIST TO THE GOVERNMENT OF WESTERN AUSTRALIA; LATE MEDICAL SUPERINTENDENT TO THE LOCK HOSPITALS, WESTERN AUSTRALIA.

THIS investigation—undertaken mainly at the instigation of Dr. J. H. L. Cumpston, then Acting Principal Medical Officer, Public Health Department, Perth—was not confined to the etiology of the disease, which is still obscure, but also included an inquiry into the means of determining when the ultimate cure of the diseased natives should be finally attained, as well as the most suitable therapeutic measures to be adopted in each case.

It is unnecessary to enter into the clinical description of the disease in its various phases, which are many, but briefly to state that the most common form consists in a granuloma, which may be grouped with actinomycosis, tubercle, syphilis, yaws, &c., in regard to its main histological features. Side by side with the granuloma, ulceration is nearly always proceeding with or without an attendant fibrosis; not always so, however, as these ulcers may heal up, leaving the granulomatous thickening as the sole evidence of the disease, or the granuloma itself may break down, leaving a putrid fungating sore, with usually a fœtid discharge.

The Etiological Factor.

The first means undertaken to discover the causation of the disease consisted in ascertaining what germs were to be found in the open lesions. As was to be expected from the fœtid discharge from a broken-down granuloma little could be made out. Staphylococci, streptococci, bacilli of all kinds with many large spirilla were constantly obtainable, but their causative rôle was most indefinite. Cultures on the usual media, agar, blood agar, blood serum, &c., produced no constant results; a great variety of germs was obtainable.

Removal of the superficial layers, with scrapings taken from the deeper portions of the indolent ulcers, where there was not much accompanying thickening of the surrounding parts, gave more definite results. Spirilla of a somewhat large size, resembling spirillum refringens, were occasionally seen. Sometimes with them, sometimes in their absence, spirochætæ identical in their morphological characteristics with Sp. pallida were found. As this method was open to the objection that these spirochætæ might be extraneous agents, removal of the ulcers with smears made from the deeper tissues occasionally showed the presence of these spirochætæ; in what percentage of cases they will ultimately appear as constant factors is too soon to state. A similar spirochæta has been described by Wise, Clelland, and others as occurring in these lesions.

Again, another parasite was sometimes in evidence, usually in the fungating, granulomatous variety of the infection, and often from the enlarged inguinal glands, when such are present. Generally seen in the large, swollen mononuclear cells, and often in considerable numbers, they possess varying appearances; if for any reason they appear crowded together the bodies resemble enlarged cocci-bacilli, sometimes kidney-shaped, not unlike huge gonococci; but when spread out, or in "spread out" mononuclear cells, there is the appearance of a differentiation into nucleus, rod-shaped, and a surrounding protoplasm.

My present opinion is that we are here dealing with two distinct diseases, or an infection of an already diseased subject with another germ. The latter organism is, presumably, the agent described by Manson as occurring in India.

Five monkeys (Macacus cynomolgus) were under observation. One, the most delicate, was left untouched, called a control. The four others were treated with pieces of tissue, removed from various diseased cases, by scarification over the eyebrows and genitals.

No. 1. A large male animal. Was in good health eight months later, having shown no lesion whatsoever.

No. 2. An adult female. Six to eight weeks after treatment a more or less typical lesion appeared over both eyebrows. Any lesion on the genitals may easily have escaped notice. Following on the disappearance of these sores, cachexia set in and the animal died from six to seven months later.

No. 3. A young female. This animal showed less marked eyebrow lesions, but also became cachectic, with local pustular eruptions, and died some months after infection.

No. 4. A young male. A somewhat similar course to No. 3.

Serum Tests.

It was thought that the most probable means of determining when a permanent cure was attained would be found on the lines of one of the complement deviation methods. After using various modifications, Fleming's amongst others, Wassermann's original technique was employed. Sheep's red blood corpuscles, being available every second day, were injected into rabbits and kangaroo-rats in various quantities. The serum obtained was inactivated. Normal kangaroo-rat serum was obtained daily and supplied the complement. Antigen was made from guinea-pig liver, kangaroo-rat liver, and granulomatous material.

Using controls for every experiment and taking the blood from nearly 40 cases, 80 to 90 per cent. of these gave the complement deviation reaction as found in syphilis. The reaction varied considerably in different cases.

Treatment: Therapeutic and Surgical.

Mercury and potassium iodide had been administered on these islands in many cases over long periods without apparent effect. Treatment by vaccines, obtained from germs found in the discharges, and also with stock streptococci, staphylococci, and B. coli vaccines was carried out, but without success. Atoxyl, arsacetin, soamin, and orsudan were injected subcutaneously over long periods; a few of these cases appeared to benefit at first, and yet the improvement was entirely temporary. Later salvarsan was injected intravenously. The value of this drug was undoubted; the beneficial effects were, in some of the worst infections, apparently instantaneous, and paved the way to a permanent cure when all other measures had failed.

Treatment latterly consisted in the use of salvarsan, supplemented by calomel and grey oil intramuscularly, followed by operation and excision of as much of the growth as possible. Grey oil and calomel were used intramuscularly alone or in alternate doses; the precise value of these preparations was indeterminate, the impression remaining that, although powerless to cause the absorption of any granulomatous growth, or even to check the spread of the ulcerative processes, yet that they acted in a beneficial manner on the organism. Hæmatological observations would be required to define this action definitely.

The employment of caustics, beneficial in some, actually harmful in other cases, has a limited range; a large number were tried, chromic acid and silver nitrate being preferred latterly.

Résumé.

The argument may always be put forward that here we are dealing with two distinct diseases. Without doubt a spirochætal or protozoal disease is present. Is there a disease distinct from this spirochætal disease? Syphilis from clinical observations alone is a complicating factor. What is the

exact etiological rôle of these bodies found in the mononuclear cells? Are they simply evidence of an active phagocytosis? (About 300 cases have been under observation over a period of 13 to 14 months.)

Australian Institute of Tropical Medicine, Townsville, North Queensland.

A NOTE ON GLAUCOMA.

BY LEONARD HILL, M.B. LOND., M.R.C.S. ENG., F.R.S.,
LECTURER ON PHYSIOLOGY, LONDON HOSPITAL MEDICAL SCHOOL.

IN his interesting paper on Theory and Practice in the Treatment of Glaucoma,[1] Mr. J. Herbert Parsons makes the following statement: "The physical conditions of the formation of lymph in other parts of the body are consistent with its production by a process of filtration out of the capillaries; the amount poured out and its chemical composition are dependent upon the difference of pressure on the two sides of the filtering membrane—i.e., the capillary wall." I think that the evidence which has accumulated on all sides in recent years controverts this statement, which is altogether opposed to the present position of physiological knowledge. The evidence is decisively in favour of the view that the flow of lymph is controlled by the activity of the tissue cells—that is, controlled by their changing and elusive physico-chemical state, or, if we choose to call it so, by their vital selective activity. I venture to say that there is no evidence which demonstrates that there is a hydrostatic difference of pressure on either side of the capillary wall. The capillaries are lined by wet protoplasmic cells and are surrounded by wet protoplasmic tissue cells. There is nothing equivalent in structure to a rigid filtering membrane. The delicate choroidal fringes in the eye hang in a bath of aqueous fluid and the cells lining the fringes secrete the fluid. Each pulsatile expansion in the arteries of the eye helps to drive a little of the aqueous into the efferent veins, and thus the effective circulation of this fluid is maintained—by secretion and the pulse.

I would say that the cause of the increased tension in glaucoma primarily is altered metabolism. The altered metabolism is produced by bacterial toxins or otherwise, and results in chemical changes in the colloids of the eye which swell by absorbing more water. Obstruction of the venous and aqueous outflow by sclerotic changes with resulting lack of oxygen and increased production of acid may well be a possible cause. Martin Fischer has shown that an excised eye becomes glaucomatous if placed in acidulated water, and to such an extent that it may burst the sclera. The presence of any salt markedly lessens the swelling produced by acid, and "subconjunctival injection of 1/8 to 1/6 molecular (4·05 to 5 41 per cent.) solutions of chemically pure sodium citrate in clinical cases of glaucoma is entirely harmless and is always followed by a prompt fall in ocular tension." The fall in tension is appreciable within ten minutes, and lasts from three to six days, with relief of all the subjective symptoms.[2] The enucleated eye placed in an acid solution shows a progressive decrease in the depth of the anterior chamber. This Fischer attributes to the unequal swelling of the colloids of the eye, those posterior to the lens swelling more than those anterior. Fischer suggests, then, that the obliteration of the so-called filtration angle is not the cause but the result of the glaucomatous condition.

The eye is to all intents an indistensile structure (unless its coats are altered by metabolic change). The increased swelling of certain tissue elements in the eye must be compensated for by a diminished volume of blood, and this entails increased pressure in the capillaries and veins within the eyeball. In such case there must be an approximation towards a rigid system of vessels, for otherwise the circulation would not be maintained. The tension of the eyeball is the capillary venous pressure which pertains in the eye of the normal or glaucomatous person. The eye, according to the varying state of its metabolism, can contain more tissue substance and less blood, or more blood and less tissue substance. It is distended with tissue fluid absorbed by the colloids in the eyeball as well as with blood, and hence the positive pressure does not wholly disappear at once when the circulation ceases. Dr. Thomson Henderson has done great service in drawing attention to the conditions which control the tension of the eyeball and the circulation, but I think he has not laid sufficient stress on the primary cause of the œdema—viz., metabolic change in the tissues.

If the primary cause of glaucoma is disordered metabolism, the best treatment is the promotion of a greater flow of tissue lymph. Just as in other acute and chronically inflamed parts incisions, congestions, cupping, &c., provoke the healing process by bringing more blood and tissue lymph, so in the glaucomatous eye that operation will be most effective which allows the most free circulation of blood and of aqueous fluid.

A CASE OF RHINITIS CASEOSA.

BY HAROLD W. WILSON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA; ASSISTANT SURGEON TO THE CANCER HOSPITAL; SURGICAL REGISTRAR, ST. BARTHOLOMEW'S HOSPITAL.

THE following case came under my care at the Victoria Hospital for Children, Chelsea, in November, 1911. At first my impression was that the child was suffering from a somewhat atypical form of nasal diphtheria. Cultivations were at once made from detached pieces of the membrane, and it was only when the absence of B. diphtheriæ (Klebs-Löffler bacillus) was reported by the Lister Institute of Preventive Medicine and further investigations had been made that I realised that I had to deal with a much more unusual condition—viz., rhinitis caseosa. Mr. F. A. Rose very kindly saw the patient with me and assisted in the examination of the material removed. The disease appears to have been discovered at quite an early stage, and the nose did not show any of the advanced and severe lesions, such as perforation of the septum and outer wall of the nasal fossa with extensive involvement of the antrum, which are recorded in several of the cases published.

The patient, a healthy-looking girl aged 11, was brought to me on Nov. 21st, 1911. Her mother, who appeared to be an extraordinarily observant woman for one of her class, stated that the child had had a yellowish discharge from the right side of the nose for ten days, and she had noticed that the right side of the nose contained some whitish material. For the last month the patient had suffered from occasional bilateral headaches, felt across the upper part of the forehead, but these had not been very marked and had not occasioned much discomfort. The child had the typical sleepy "adenoid" facies and the bridge of the nose appeared flattened out. There was a high arched palate, but no evidence of tuberculosis or congenital syphilis. No tenderness over the frontal sinuses or maxillary antra could be elicited. Tonsils natural. Tonsillar lymphatic glands just palpable. Adenoids: a firm pad on the roof of the nasopharynx. Nose: left side natural. After syringing out a certain amount of muco-pus with an alkaline lotion from the right side the following appearances were noted. Vestibule natural. On the outer wall of the nasal fossa in the middle turbinate region was a yellowish-white "membrane." In extent it measured, roughly, about 1 in. by ½ in., with its centre over the middle turbinate bone and its long axis directed from before backwards. It extended forwards for a very short distance on to the atrium, and did not reach the inferior turbinate in a downward direction. The "membrane" was distinctly raised above the surface and had a very definite anterior border. In the latter situation the surrounding mucous membrane showed an abrupt bright red line of injection, which reminded one very much of the appearance of a "line of demarcation." The mucous membrane covering the remainder of the atrium and septum appeared healthy.

With a pair of nasal forceps it was found possible to detach and remove almost all the "membrane," and when this had been done, except for several small oozing points and, here and there, a slight abrasion, the surface of the underlying mucous membrane appeared healthy and was quite free from ulceration. A week's subsequent syringing with an alkaline lotion completely cleared away any scraps of material which still remained, and the nose at the end of that time appeared quite normal.

By trans-illumination the left antrum was seen to be

natural. The right antrum was translucent, but not so clear as on the left side. Infra-orbital and nasal taches were visible but not very distinct. These appearances, I think, could be satisfactorily accounted for by a certain amount of catarrhal thickening of the lining membrane.

The material removed had a slight fœtor and appeared more like putty than anything else. It was greyish in colour and of a soft, friable consistency, but at the same time was different from the ordinary caseous material one associates with tuberculous disease. Microscopically the bulk of the mass was seen to consist of large numbers of long fine needles, mixed with a structureless material, the former probably of a fatty nature, as they stained well with Sudan III. In addition there were numerous micro-organisms, a few pus cells, and a few small crystals. No mycelial threads could be found. The cultivations taken showed a short-chained streptococcus and staphylococcus pyogenes aureus.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Missed Labour.—Rhabdo-myosarcoma of the Uterus.—Relative Size of the Uterus in Cases of Hydatidiform Mole.—Exhibition of Specimens.

A MEETING of this section was held on Jan. 4th, Dr. AMAND ROUTH, the President, being in the chair.

Dr. W. C. SWAYNE (Clifton) read a paper on Two Cases of Missed Labour. Spiegelberg defined missed labour as being the occurrence of the nisus of parturition at or about term, with the subsequent evacuation of a dead or decomposed fœtus either by nature or by art. The first case described was one by Oldham in 1847. The period of retention varied greatly. Hagmann described one case in which delivery by Cæsarean section was necessary, the fœtus being retained in the uterus for 440 days after the last menstruation, or about five months after term. The condition was a rare one, only 15 cases having been collected by Hagmann in 1904. In Dr. Swayne's first case the patient, who had had three previous pregnancies, last menstruated on Oct. 16th, 1904. On June 10th, 1905, she had a flooding, and on the 24th the liquor amnii was discharged, and a mass expelled which the midwife attending recognised as placenta. She ligatured and cut the cord. This was followed by an offensive purulent discharge, and on August 8th a portion of the fœtus began to come away per vaginam. The patient was admitted to the Bristol Royal Infirmary in a very grave condition, semi-comatose, and the uterus was found to be enlarged to the size of a six months pregnancy. The contents of the uterus, which were decomposing, were removed with great difficulty after dilating the cervix, but in spite of all restoratives the patient sank the same evening. In Dr. Swayne's second case the patient last menstruated on Dec. 17th, 1906. On Sept. 17th, 1907, the patient had slight pains and uterine contractions, but these soon passed off, and nothing more occurred till Nov. 30th, 1907, when Dr. Swayne was sent for. Labour had begun and the os was dilating. Owing to the large size of the child delivery had to be effected by craniotomy. The child was retained for 340 days after the last menstruation, and weighed 14 lb.

Dr. W. BLAIR BELL (Liverpool) read a paper on a case of Rhabdo-myosarcoma of the Uterus. A patient, aged 70, had the menopause 20 years ago and remained quite well until July, 1911, when she noticed a slight reddish discharge from the vagina, which was not offensive then but became so later. On Sept. 15th she passed a large piece of growth, which was found on histological examination to be a mixed-cell sarcoma. The uterus, tubes, and ovaries were removed a few days later, and the patient made a good recovery. Ten weeks later she was suffering from intestinal obstruction and the abdomen was found to be full of growth. Enterostomy was performed and the patient lived for about a week. The specimen removed showed the uterine cavity to contain a large polypoid growth, round which the wall of the uterus was stretched. On further examination the tumour proved to be a mixed-celled sarcoma, in which there were a large number of broad spindle cells, and some of them were striated muscle cells of a somewhat embryonic type. The recurrent growth in the abdomen was also found to be a mixed-celled sarcoma.

Mr. HENRY BRIGGS (Liverpool) read a paper on the Relative Size of the Uterus in Cases of Hydatidiform Mole, with illustrative cases and specimens. Amidst the ample available evidence that the clinical features of cases of hydatid moles have, in the main, been accurately stated by obstetrical writers, the author proposed to discuss only one feature—the relative size of the uterus in cases of hydatid mole, and to produce clinical reports of 23 cases and the specimens collected by him chiefly from his own practice during the past 18 years in support of the following conclusions. Firstly, that the uterus in size was very rarely, and then only temporarily, proportionate to the period of pregnancy (only 1 case in the 23), and was almost invariably disproportionate, in 16 of the cases being undersized and in 4 of the cases being oversized. Chorion-epithelioma was present in two cases—in one undersized, in the other oversized. Secondly, Mr. Briggs contended that in almost all cases in which there was either abnormal uterine tension or a rapid increase in the size of the uterus, the retained blood or intra-uterine hæmorrhage ought to be considered. A complete clinical report of the 23 cases embodied in the paper was then given.—Dr. W. S. A. GRIFFITH drew attention to the unreliability of the measurements of the size of the uterus when taken in relation to the navel, for whereas the usual height of the lower border of the navel was 6 inches above the pubes; in a considerable number of women it measured from 5 to 7 inches. Added to this was the difficulty of certain knowledge of the duration of pregnancy. At the same time he was quite prepared to agree with Mr. Briggs that a uterus containing a cystic mole was often smaller than a normal pregnant uterus of the same period. Dr. Griffith was not surprised that Mr. Briggs avoided the question of diagnosis. His own experience was that when the cervix was closed his diagnosis had usually been at fault.—Dr. G. BLACKER, after expressing appreciation of Mr. Briggs's paper, said that for a long time past he had taught that the size of the uterus might be greater or less than, or equal to, the size of the organ at the corresponding period of pregnancy. Mr. Briggs's paper brought out the fact that in a considerable number of the cases the uterus was definitely smaller than it ought to be. At the same time he thought that in many of the cases quoted the mole had been retained some time in the uterus, and this might explain the apparent anomaly. During the period of retention the mole may have undergone retrogressive changes and shrinkage. He gathered from some of the specimens in which the uterus was larger than normal that the author of the paper thought some of this increase due to the presence of hæmorrhage in utero, but the case of hydatidiform mole he had shown before the section proved conclusively that the undue enlargement was due to the size of the mole itself. The matter was of great clinical interest, and he thought Mr Briggs had quite proved his point.—The PRESIDENT had seen several cases of hydatid mole where the uterus was not enlarged beyond the supposed period of gestation. He was surprised that one of the cases of chorion-epithelioma had been preceded by one of the smaller varieties of hydatid mole. He had thought it probable that the larger hydatid moles, showing more activity of growth and greater vascularity, were more liable to develop chorion-epithelioma than the smaller and more quiescent ones. He congratulated Mr. Briggs on his valuable contribution to their knowledge of the subject.—Mr. BRIGGS, in reply, admitted the difficulty, and sometimes the impossibility, of substantiating statements as to size changes in the uterus. These drawbacks, however, cut both ways, affecting oversize and undersize, principally in changes of slower and lesser degrees, but the predominance in the long run would come out. Mr. Briggs explained that he had himself tardily yielded to an 18 years' acquaintance with undersize, because he had seen it repeatedly verified, and the intra-uterine hæmorrhage recently observed in Case 1 encouraged further inquiry.

The following specimens were exhibited:—

Dr. ROBERT WISE: Cervical Tube to be left in the cervix after dilatation.

Dr. R. DRUMMOND MAXWELL: Angio-chorioma of Uterus.

Dr. BLAIR BELL: (1) Exfoliation of Endometrium during

Menstruation; and (2) Bilateral Solid Tumours of the Ovary, probably carcinomatous sarcomata.

PATHOLOGICAL SECTION.

Two Cases of Amaurotic Idiocy.—Micrococcus Zymogenes in a Case of Malignant Endocarditis.—Phagocytosis from the Adsorption Point of View.

A MEETING of this section was held on Jan. 16th, Professor R. T. HEWLETT, the President, being in the chair.

Dr. J. TURNER read a paper on two cases of Amaurotic Idiocy or Tay-Sachs Disease. The first case was that of a Jewish girl, aged 13. She was the youngest of 12, of whom the first ten were born dead, or died at birth, or only survived for a few months. For two years before her death she had been subject to epileptiform fits, sometimes having as many as seven in the day. She had marked amblyopia with contraction of the fields of vision. The fundus was not reported upon. Post mortem the brain was very firm and showed marked atrophy of the convolutions. The microscopical appearances were pathognomonic of amaurotic idiocy. The second case was that of a boy aged 5, and was the first case yet published out of upwards of 100 reported, which occurred in a child not of Jewish extraction. He was undeveloped and unable to stand or talk, and had no thumbs. His sight was not tested, nor were his fundal appearances noted. After death the cerebral gyri were found to be shrunken and tough and discoloured brown in the right superior parietal lobe. The cortex was narrow and dark-coloured. The central canal of the cervical cord was dilated for a short distance. Sections of the grey matter stained by the author's pseudo-vital method showed that the ganglion-cells were chiefly affected. Many darkly stained intercalary nerve-cells were also seen, which appeared fairly intact, and from which a large number of beaded intercellular neurofibrils were observed. The histological changes generally were those of amaurotic idiocy. The cases were exceptional because of the ages of the patients, and the case occurring in an English child was unique in the literature. There were signs suggestive of congenital syphilis in both cases.

Dr. J. A. BRAXTON HICKS read a paper on an Unusual Organism (Micrococcus Zymogenes) in a case of Malignant Endocarditis. He stated that the organism was first described in 1899 by two Americans, MacCallum and Hastings, and subsequently by Harris and Longcope and Birge, also American writers. He could find no other references to it in continental or English literature, and he believed that the present case was the first account of its isolation recorded in this country. After a description of the clinical history of the case, which was one of multiple infarctions ending in cerebral embolism and death, he proceeded to describe the character of the organism isolated during life from the patient's blood. The organism was a Gram-positive, non-motile coccus growing well on agar media in somewhat coarse streptococcal-like colonies. It slowly liquefied gelatin, produced acid from the sugars but no gas, grew feebly or not at all on potato. Blood serum allowed growth, but there was no liquefaction of the medium, such as has been described in some of the cases. Its typical growth was seen in litmus milk, which became decolourised and clotted. The clot then liquefied gradually, the upper layers becoming tinged red. The tinging and liquefaction proceeded and spread downwards and the remains of the clot sank to the bottom of the tube as a precipitate, and this also became tinged red. The final picture was a deeply red-stained precipitate at the bottom of the tube, with a faintly pinkish yellow, clear, supernatant fluid. Injection into white mice only caused illness from which they eventually recovered. Guinea-pigs were unaffected. The organism resembled that described by the American writers, who, however, had found that its growth on potato and its pathogenicity were not constant features, as sometimes it neither grew on potato nor killed white mice, which appeared, of all animals, to be the most susceptible to it. Typical specimens of the cultures were shown.

Dr. J. C. G. LEDINGHAM gave a communication on Phagocytes considered from the Adsorption Point of View. The experiments described were entirely of a quantitative nature and dealt with the relations subsisting between "free" and "bound" opsonin or "free" and "phagocytosed" bacilli, as the concentration of serum or of bacilli altered. He showed that the sensitisation of organisms for phagocytosis could most closely be expressed by an adsorption formula. In the case of phagocytosis of sensitised bacilli suspended in saline solution a similar adsorption process was probably at work, and the value of "1/n" in the adsorption formula ($T/m = k \times {}^{1}/_{n}$) appeared (in this case) to approach unity very closely. The author stated that the experiments were to be regarded as a preliminary contribution to the subject.

LARYNGOLOGICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Jan. 12th, Mr. T. MARK HOVELL (Vice-President) being in the chair.

Dr. ANDREW WYLIE showed a case of Paralysis of the Left Vocal Cord in a woman, aged 21 years, which raised the question of recurrent paralysis as a consequence of injury to the recurrent nerve in the neck. The exhibitor had removed an adenoma of the thyroid gland without any benefit so far as the paralysis of the cord was concerned.—Several of the members cited cases of recurrent paralysis which had followed contusions of the neck.

Dr. WYLIE also exhibited a case of Multiple Laryngeal Papillomata in which repeated removal of the growths had failed to bring the disease to a standstill.—The advisability of thyrotomy in such cases was discussed and negatived by most of the speakers. The use of carbon dioxide snow, as a cauterising agent, applied to the bases of the growths after removal was suggested.

Dr. WYLIE also showed another laryngeal case in which a Hard Horny White Growth on the Right Vocal Cord was regarded as malignant, although probably of a mild type.—Mr. HOVELL commented upon the rarity of the appearance and cited a case under his own care in which, after twice being removed endolaryngeally, the growth did not recur.

Dr. W. H. KELSON showed a case of Swelling of the Right Ventricular Band of the Larynx in a syphilitic subject. Iodide of potassium had been administered without effect, but Dr. Lieven (of Aix-la-Chapelle) advised the use of salvarsan, coupled with the energetic inunction of 6 to 7 grms. of unguentum hydrargyri as likely to prove of service.

Dr. W. JOBSON HORNE showed a case of Atrophic Rhinitis with Nasal Obstruction in a child aged 7 years.—Mr. H. CLAYTON FOX expressed himself as being in favour of cold paraffin injections in the treatment of this disease.

Mr. E. B. WAGGETT and Mr. EDWARD D. D. DAVIS exhibited a case of Hyperostosis Cranii or Leontiasis Ossea, with symmetrical osseous swellings involving the nasal processes and bodies of the maxillæ, with radiograms showing the extent of the osseous deposits there and also in the nasal cavities. There were no signs or history of syphilis, but the Wassermann reaction was positive, a fact commented upon by various speakers with reference to the etiology of the disease.

Dr. DAN MCKENZIE exhibited two children who had suffered from Tuberculosis of the Retropharyngeal Lymphatic Glands. Abscesses had formed in each case, one pointing in the posterior pharyngeal wall, and the other behind the sterno-mastoid in the neck.

Mr. FRANK A. ROSE (for Mr. W. D. HARMER) showed a woman, aged 61 years, with a Swelling in the Region of the Left Tonsil ulcerated on its antero-inferior surface, which was referred by the patient to an injury caused by a crust of bread which had stuck in the tonsil.—Divergent opinions were expressed concerning the probable nature of the tumour.

Dr. J. DUNDAS GRANT presented a case of Tuberculous Laryngitis, showing an acute herpetoid appearance in the shape of small blisters on the infiltrated left side of the larynx, which later became oval lenticular ulcers. The condition had caused intense pain which was relieved by the inhalation of equal parts of anæsthesin and orthoform.

MEDICAL SOCIETY OF LONDON.

Exhibition of Clinical Cases.

A MEETING of this society was held on Jan. 22nd, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. A. C. D. FIRTH showed a case of Myoclonus (Paramyoclonus Multiplex). The patient was a boy. Two years ago the child received a severe fright. Soon after this

occurrence the movements were noticed. The child had never had any fits, and no history of epilepsy could be obtained in the family. His brothers and sister were normal. The contractions had been observed in the orbicularis palpebrarum, platysma, the trapezius, the lower fibres of the pectoralis major, the lower fibres of the deltoid, the triceps, the supinator longus, and the rectus femoris. The contractions of the orbicularis palpebrarum were synchronous and exactly resembled a tic; the contractions of the other muscles were symmetrical but not synchronous, and varied much in the frequency of their appearance, at times several contractions in the minute, at other times one contraction only in several minutes, whilst sometimes a muscle in which the spasms had previously been observed was quiet. The movements were most constant in the triceps and the supinator longus. Emotional disturbance appeared to increase the number of contractions. Nystagmus was not present, but both eyes showed evidence of a severe attack of ophthalmia neonatorum. The knee-jerks were brisk, but there was no spasticity of the limbs and no clonus could be obtained. The electrical reactions of the muscles were normal. The case had been under observation for nine months, and no alteration in condition had been noticed.

Dr. F. PARKES WEBER showed a case of Chronic Œdema of the Right Lower Extremity of uncertain origin. The patient was an unmarried English woman, aged 29 years, who said she had always enjoyed good health. She was well built and active, and the only discoverable abnormality about her was the presence of chronic œdema of the right lower extremity. This œdema extended from the foot upwards to the inguinal fold in front and the gluteal fold behind. The parts above were not affected. There was no evidence of anything abnormal in the thoracic or abdominal viscera, in the superficial lymphatic glands, or in the urine. Her thyroid gland appeared well developed. There was no family history of any similar localised œdema. She had never been out of England. The swelling had first appeared about two years ago in the lower part of the limb, and afterwards had gradually extended so as to involve the whole limb. There had never been any erysipelas, but six months ago there had been some redness of the affected limb. If the patient rested in bed the œdema gradually disappeared, but returned when she got up again. Bandaging the limb (or possibly the pressure of an elastic stocking) seemed to be the only practical method of opposing the œdema when she was up. Thyroid treatment had been tried with a negative result. In the case of a young woman, aged 23 years, with chronic œdema of the left lower extremity, shown by Dr. Parkes Weber at the Clinical Section of the Royal Society of Medicine, lymphangioplasty, after Handley's method, had been tried but had failed.[1] In that case, however, the œdema seemed to have been of congenital origin.

Mr. E. MICHELS and Dr. F. PARKES WEBER showed a case of Multiple Polyps of the Large Intestine with Toxæmic Symptoms; appendicostomy. The patient, a Jewish girl, aged 17 years, was the tenth of 11 living children (four others died) of her father by his first wife. Four or five years ago she began to suffer from attacks of diarrhœa and to notice occasional protrusion of a lump from the anus. The attacks of diarrhœa used often to continue for weeks at a time. On admission to the German Hospital on April 24th, 1911, it was found that the mucous membrane of the rectum and sigmoid flexure was studded with soft sessile or pedunculated tumours, some of them as large as a hazel-nut, but most of them considerably smaller. They extended from close to the anus to as high up as one could feel by digital examination or see with the sigmoidoscope. There was continual diarrhœa and the patient's urine contained excess of indican. In the hospital, treatment by drugs and rest in bed failed to stop the diarrhœa, and the patient looked emaciated and very weak. Sometimes there was moderate fever. A blood examination on April 26th gave: hæmoglobin, 45 per cent.; red cells, 3,890,000 per cubic millimetre; white cells, 10,500; stained blood-films showed nothing special. In May some of the polyps seemed to have become gangrenous, and a small one, which came away during rectal examination, was found to consist of glandular tubules (lined with columnar epithelium) and an interstitial fibro-cellular connective tissue, consisting chiefly of cells. On June 1st, Mr. Michels performed an appendicostomy operation, and the large intestine was regularly washed out through the appendicostomy opening, at one time with a weak protargol solution. This seemed to have lessened the diarrhœal tendency and to have relieved the toxæmic condition, but the polyposis of the large intestine, as far as could be made out by digital examination of the rectum and the use of the sigmoidoscope, persisted as before. Yet the patient felt much better and had gained considerably in weight since the operation. The appendicostomy opening was still being kept open.

Dr. F. S. PALMER showed a case of Bulbar Paralysis. It was that of a house painter, married, with children, who had been admitted to the West End Hospital on Jan. 13th, 1912, suffering from chronic nuclear (labio-glosso-laryngeal) paralysis of seven months' duration. Beyond the ordinary ailments of childhood he had never had any serious illness until last summer. He had never had diphtheria, scarlet fever, or enteric fever, and syphilis was denied. The present illness had commenced early in July last, with stiffness in the muscles of the neck, weakness in the movements of the tongue, and articulatory difficulties, followed late in September by impairment of deglutition and constant drooling of saliva. About the same time he had complained of colicky pains in the abdomen, which after a short period of a few days had disappeared. The other symptoms had, however, been steadily, if not rapidly, progressive, and he was only able to swallow liquid food; and that with difficulty. He was very emotional, complained of headache, chiefly occipital, and his facies reflected a condition of suffering and anxiety. There were marked weakness and wasting of his facial muscles, with an appearance of exophthalmos but without any palpable thyroid enlargement, tremor, or tachycardia. His pupils were unequal, the left greater than the right, but both reacted to light and to accommodation. The optic discs were normal. His tongue could not be protruded beyond the dental arch, was wrinkled and atrophied, and sometimes exhibited fibrillary tremors. His speech had a distinctly nasal intonation and was almost unintelligible. The palate was motionless on phonation. A decided blue line could be traced along the gums, but he had no wrist-drop or other signs of plumbism. His mouth was usually open, he was unable to whistle or blow, and there was a good deal of saliva dribbling. The small muscles of his hand showed definite signs of wasting, the atrophy being particularly seen in the right thenar and hypothenar eminences. His gait was practically normal and there was no sign of spasticity in his limbs. No Rombergism was present. The plantar reflexes were flexor on both sides. The supinator reflexes were brisk and the knee-jerks increased. A definite jaw-jerk could be elicited. The sphincters showed no loss of control. Dr. T. Braxton Hicks had reported that the Wassermann reaction of the blood and cerebro-spinal fluid was negative. The cerebro-spinal fluid showed 206 lymphocytes to the cubic millimetre. The urine contained a large quantity of urates and gave a marked reaction for indican. Its specific gravity was 1036. There was no albumin or sugar. The centrifuged deposit showed a small number of leucocytes and one or two granular casts.

Mr. W. G. HOWARTH and Mr. E. M. CORNER showed a case of Dysphagia in a child. In June, 1908, the child, aged 4, was playing in the street when a neighbour noticed her trying to vomit. She was taken to Guy's Hospital and a week later was admitted for "stomatitis" accompanied by some ulceration. She was thought to have swallowed some corrosive substance. She was admitted to St. Thomas's Hospital two months later, in August, 1908, with a history of dysphagia since June. Under full anæsthesia and with an œsophagoscope bougies could not be passed further than a point 8 inches from the teeth. With X rays it was seen that bismuth stopped at the level of the third rib and began to trickle in drops down the œsophagus. Gastrostomy was performed by Mr. Corner in August, 1908. The child went to an infirmary in November, 1908. After a while the "stricture" relaxed and a bougie passed. The stricture was dilated and the gastrostomy wound allowed to close. When exhibited the child could eat ordinary food. Examination of the œsophagus showed that at a point just below the cricoid, 19 cm. from the teeth, several small whitish patches

[1] THE LANCET, Dec. 25th, 1908, p. 1877.

were present in its wall. These did not appear to form a ring and caused no projection into the lumen of the œsophagus. There was no narrowing of the lumen, and the mucous membrane in the rest of the œsophagus appeared perfectly normal. It seemed, therefore, that the impassable "stricture" of September, 1908, had disappeared (1912), and it was suggested that the cure of the patient was due to the splitting of the stricture by dilation in a growing subject, the growing epithelium grafting the "splits" which showed as discontinuous small white patches.

Mr. A. E. BARKER showed a case of Plexiform Neuroma. It occurred in a boy, aged 14, and had apparently been present for several years and was quite visible in a photograph taken at the age of 4. Its distribution was roughly that of the facial nerve. A piece, of the size of a walnut, had been excised in order to modify the severity of a marked ptosis which was present. Microscopically at first medullated nerve fibres had been seen, but subsequent sections of the same piece failed to show them.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Postponed Discussion on Vaccine Therapy.—Trauma as a Factor in Disease.

A MEETING of this society was held on Jan. 17th, Mr. J. M. COTTERILL, the President, being in the chair.

In the discussion on Vaccine Therapy, adjourned from the meeting held on Nov. 29th,[1] Dr. G. LOVELL GULLAND said that one must endeavour to eliminate auto-suggestion. He had had most experience with the injection of tuberculin, which was very satisfactory in the treatment of glands. But if they were in the stage of breaking down, or if there was much periadenitis present, then tuberculin treatment was not suitable and surgical interference was necessary. Where there were masses of glands in the neck without much periadenitis, but the patient was losing weight and in poor health, vast improvement had resulted from the use of tuberculin as the sole means of treatment. He commenced treatment always with a dose not large enough to give a reaction, but he continued these injections for a long time. In pulmonary cases his practice was not to use tuberculin when the case was going on well. It was unwise to employ tuberculin in febrile cases, and he had found that the smallest dose did harm. He had found tuberculin most useful in what might be termed "stuck cases," or those in which improvement became arrested, and also in those very chronic cases where the condition of the lungs was largely fibroid often surprisingly good results followed. In tuberculosis of the kidney and bladder he had found it useful. He had steadily used tuberculin T.R. because he had found that it gave good results. The constant use of one preparation alone allowed one to know its potentiality perfectly. One ought always to commence with very small doses so as never to produce a rise of temperature. He rarely employed a larger dose than 1/2000 mg. Exceptional care was necessary in children, for tuberculin was much more active in them. He was quite convinced that tuberculin given by the mouth gave good results if administered in the early morning on an empty stomach and well away from feeding time. In septicæmia, especially puerperal, his experience with vaccines had been most disappointing; he had had much better success with antistreptococcus serum. He even thought vaccines definitely harmful in such cases. There was rarely time to prepare an autogenous vaccine. He discussed vaccine treatment also in ulcerative endocarditis, where he had not found it successful, and in gonococcal infection, where very varying results were obtained.—Dr. THEODORE SHENNAN had observed a great number of cases of mixed infections in which the B. proteus had been found. Was this a pathogenic organism or did it merely assist the action of other organisms? He had been giving a vaccine of this organism along with others. Most encouraging results had been obtained with the micrococcus catarrhalis, especially when in relation with pneumococci; it seemed not only to clear off the disease but to ward the patient against succeeding catarrhs.—Dr. I. STRUTHERS STEWART alluded to the relief of pain which the injection of streptococcic vaccine often produced, and to the fact that old sinuses frequently healed after a few inoculations. Bronchitis was often due to streptococcus infection, and he had found vaccine injections most satisfactory in its treatment. There was an increase in the amount of sputum for some days subsequently, and this was followed by a diminution. A secondary increase in the amount of sputum was an indication for another inoculation. He also discussed the results of vaccine therapy in acute tonsillitis, pneumonia, and cystitis, from his own experience.—Dr. L. C. PEEL RITCHIE said that there might be a reaction against the employment of vaccine therapy because of the many disappointments, but he thought that it should be the routine treatment in all cases of micro-organismal disease. He thought, however, that there was a chaos as regards dosage and that the enumeration method was at best merely a makeshift. A uniform standard could be obtained by weighing the solid organisms. In his experience gonorrhœal urethritis was little benefited by inoculation, while the arthritis was greatly benefited.—Dr. R. CRANSTON LOW said that in the Dermatological Department of the Royal Infirmary they used stock vaccines in staphylococcic infections, and only where these produced no effect did they employ autogenous vaccines. They never made use of the opsonic index. In furunculosis results were good. If a patient had several boils these nearly always got worse after an injection, probably because the patient was getting a sufficiency of his own vaccines. He found that greatly smaller doses were quite as beneficial as the large ones formerly employed. In sycosis one must give at least 20 injections to obtain good results. Acne was not related to staphylococcal invasion, and therefore a mixed vaccine was required. Of the tuberculous cases the majority were lupus cases, and he could not record a single cure with T.R. in 1000 mg. dose given once in two weeks; merely a diminution in the amount of infiltration took place. A bacillary emulsion gave no better results. Dr. Low said that one should not rely on vaccine treatment alone and that the treatment should be prolonged.—Dr. W. E. CARNEGIE DICKSON said that in estimating the dosage one had to consider the virulence of the strain and so to select a certain strain for each case. As regarded B. coli infection in children, some cases did well with vaccines while others were really harmed. It was most necessary to get the vaccine from a reliable source; he knew of two cases where generalised disease had been produced by the inoculation of non-sterile vaccines—e.g., a case of pyæmia caused by Coley's fluid.—Dr. C. W. D. WILKIE said that in cases of peritonitis already developed vaccines produced no improvement and, indeed, would only lower the resistance of the patient. In such cases serum therapy was more indicated than vaccine therapy.—After Dr. DINGWALL FORDYCE and Mr. WILLIAM STUART had spoken Dr. JAMES RITCHIE replied, and said that it seemed generally agreed that a case had been made out for the further use of vaccines in therapeutics, and that the only practicable method of judging of their efficacy was the clinical one. He emphasised the unsatisfactory character of the methods of standardisation in use, in that none of them took account of the individual potency of the strain of an organism used for the preparation of the vaccines. He again laid stress on the empiricism of treating diseases of unknown origin by means of vaccines.

Dr. ALEXANDER JAMES read a paper on Trauma as a Factor in Disease. He said that when an ordinary bar magnet received a heavy blow from a hammer its magnetism could be adversely affected as a result of the change produced in its molecular condition. According to the violence of the blow the demagnetisation would vary in completeness, and as a consequence there would be variation in the power of its recovery. In the same way, when a living tissue was subjected to a concussion its vitality could be diminished or lost temporarily or permanently. This molecular change might be induced by other traumas besides concussion. Thus, chemical shock, as from exposure to noxious gases, electricity, extremes of heat or cold, or psychical shock, might all be met with. The most far-reaching effects were produced, however, when the nervous tissues were the seat of injury. Thus, concussion of a muscle could impair the power of that muscle temporarily or permanently, while concussion of the brain or cord not only impaired or abolished function at the affected part much more easily because the tissue was more delicate, but because the brain and cord were the governing and trophic radiating tissues it could impair and abolish

[1] THE LANCET, Dec. 9th, 1911, p. 1625.

function in every other part of the body. Anything which disturbed function in any part of the nervous system might have far-reaching effects. Thus a condition of onychia was produced in the thumb, index and middle fingers, of a girl, aged 19, as a result of nerve disturbance. At the beginning of the disease the fingers felt cold and numb with pain which extended up the arm and which was increased on movement. The disease had persisted for seven years. Investigation of the cause showed that as a result of several operations for bone disease in the neighbourhood of the elbow joint there was extensive cicatrisation which had induced nerve kinking and irritation. On cutting down the median nerve was found in an abnormal situation and bound down to the internal aspect of the elbow-joint and fixed in a mass of cicatricial tissue. The nerve was freed, with the result that nine weeks later complete recovery had taken place. He reported also a case of left-sided facial hemiatrophy following on a slight wound of the cheek; a well-marked case of Raynaud's disease consequent on the passage of a Mauser bullet through the metacarpo-phalangeal joint of the middle finger of the left hand; and one in which wasting of the left leg and thigh, with extreme weakness, resulted from a slight injury to the left tarsus by the hoof of a pony. Complete recovery ensued in the second case on amputation of the affected part and freeing the nerves from their inclusion in cicatricial tissue, and in the third case on amputation of the foot. Dr. James next drew attention to diseased conditions set up by irritation of nerve centres. A miner, aged 35, complained of stiffness in the back and weakness, with the development of swelling under the skin of the trunk, subsequent to an injury on the back. His voluntary power, especially in the right arm, was impaired, and the plantar, abdominal, and epigastric reflexes were absent, and numerous lipomata had formed on his trunk. He died about a year subsequently, after the muscles of the legs had become wasted and paralysed. The brain shock might be psychical, not mechanical, as happened to a station-master who, in endeavouring to prevent a collision, suffered from great nervous shock, and a month later developed paralysis agitans. Fright in being prepared for operation and from other causes had caused death. Every physician of experience recognised the powerful influence of mental conditions on organic functions and disease. Of 27 cases of locomotor ataxia, 9 gave a history of accident, and of these 2 seemed to have some effect on the disease. Of 40 cases of lateral and disseminated sclerosis, 11 gave a history of accident, and 6 of these might have had a causal relationship to the disease. Of progressive muscular atrophy Dr. James had 13 cases, in 3 of which accidents had occurred, but in only 2 was a relationship possible. Of 12 cases of paralysis agitans, in 2 there was a history of what might be called accident; in one case a male patient had had the ring finger of his right hand amputated on account of ascending septic poisoning 26 years previously. The right hand had been rather shaky ever since, but it was only a year ago since it became so troublesome as to interfere with his work and to extend to his left arm. In these and similar ways trauma might be a cause of disease and impaired health. There was no doubt, however, that trauma might appear to be this and yet not be so. It might be simply a factor varying indefinitely in potency in bringing to light a previously existing disease. It was the doctor's duty to find out as accurately as he could what the accident was and what had been its effects on the individual. To enable the doctor to do his duty he must ascertain the precise nature and degree of the injury, and he must know what the effects on living tissues of all the different forms of injury could possibly be. He must further know the patient's heredity, constitution, habits, circumstances, and previous health. He must carefully investigate the symptoms and judge as to how what is merely subjective tallies with what is objective. Time would help him greatly. A study of cases showed that if hysteria and neurasthenia were eliminated a distinct injury did not often go on for very long without causing objective signs of disease. In all cases the doctor must take notes of the patient's mental attitude. In these days an accident is often simply a commercial asset to be negotiated with to the last shilling, and the average man in his anxiety to negotiate to the best advantage might by thinking too much on his symptoms do himself infinitely more harm than the accident itself could ever have done. It had been argued that medical inspection of workmen should become general; for this something might be said, but it must be remembered that men affected with chronic disease might still be excellent workmen, and, moreover, that as a diseased condition might easily be missed, an unsound man might easily get the imprimatur of soundness. In compensation work Dr. James's own idea was that it would be best if the medical men concerned could meet by themselves and come to a conclusion which could be put before the judge.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Chorion Epithelioma with Secondary Deposits.—Myoma undergoing Sarcomatous Degeneration.—Expulsion of a Papyraceous Fœtus before a Living Child.

A MEETING of this section was held on Jan. 5th, Dr. A. J. HORNE, the President, being in the chair.

Dr. H. JELLETT recorded a case of Chorion Epithelioma with Secondary Deposits. The patient, aged 39, was admitted to the Rotunda Hospital on Sept. 3rd last. She had been married for 12 years, and had had seven children and one abortion. She believed her last pregnancy to have terminated in June, 1910, but on questioning her she said that she had not menstruated between January and May, 1911, and that in May she had had severe hæmorrhage, which had since been constant. On examination the following day the uterus was found normal in position and enlarged to size of two months' pregnancy. On the walls of the vagina were three small swellings, purplish in colour, and resembling small hæmatomata or thrombosed veins. A diagnosis of possible pregnancy was made, and one of the swellings was removed for examination. Dr. R. J. Rowlette reported that they were cystic masses filled with blood clot. The surface epithelium was regular, and the deeper tissues were infiltrated by masses of very irregular flat cells with large blood spaces. He diagnosed chorion epithelioma or mixed-celled sarcoma. On Sept. 11th the uterine cavity was explored and pieces were curetted for examination. These were found to be of a similar character to the vaginal swellings. The next day the patient had a cough with expectoration containing a considerable quantity of blood. A diagnosis of chorion epithelioma was then made. On the 14th the uterus and ovaries were removed as extensively as possible. The uterus was enlarged to the size of a small fœtal head, with a very distinct tumour on its left side. The patient stood the operation well, but her lungs rapidly got worse, and she died two days later. At the necropsy the lungs were found to be studded all over with small tumours, corresponding in appearance and characteristics with the uterine tumour and the vaginal metastases. The uterine tumour and all the metastases consisted of blood and infiltrating masses of cells derived from Langhans's layer. There were no syncytial masses and no pieces of chorionic villi. A portion of the tumour was submitted for diagnosis to Professor Pick, of Berlin, who confirmed Dr. Rowlette's diagnosis of chorion epithelioma derived practically entirely from Langhans's layer.—Dr ROWLETTE said the case was interesting from the pathological point of view, being not quite typical. The tumour seemed to consist of one set of cells—i.e., Langhans's layer—and not of other parts of the ovum, as generally occurred. In this case no villi were to be found.—Dr. NINIAN FALKINER said that according to his information this disease was identified about 1888 by Dr. Sangar, of the United States. Out of a record of 127 cases the mortality was 59 per cent.—Dr. GIBBON FITZGIBBON referred to a case shown in February, 1904, where the symptoms of the disease developed after the removal of a hydatidiform mole. The uterus was removed, and the condition diagnosed as chorion epithelioma. There were no metastases, and the patient was quite well 12 months afterwards.—Dr. JELLETT replied.

Sir WILLIAM SMYLY related a case of Myoma undergoing Sarcomatous Degeneration. He said that his views with regard to the treatment of myomatous tumours of the uterus had undergone a gradual change. He operated more frequently and resorted to conservative measures more readily than he used

to do. Almost every case that required treatment he considered was best treated by operation. Myomectomy, which, owing to improved methods of suturing and the introduction of rubber gloves, was scarcely more dangerous now than hysterectomy, should be generally adopted in women within the child-bearing period of life. He reported a case in which a myoma had been diagnosed 20 years previously and had caused little inconvenience until about Christmas, 1910. In April operation was performed. The primary result was good, but after a few weeks the disease again began to show its presence, and the patient died in about four months. The lesson that he drew from this case was the importance of early interference.—Professor ALFRED J. SMITH said to a certain extent he would recommend operative treatment in fibromyoma of the uterus, but he would treat each case on its merits. If a patient had been recently married an interval of one or two years would be a safe margin to allow her to run without taking any risk, provided the tumour was not increasing or causing trouble.—Dr. JELLETT thought, speaking generally, if a married woman within the child-bearing period had a myoma of the uterus which would not prevent pregnancy going to the full term it could be removed by myomectomy, and the operation was indicated. If it was found at the time of the operation that the tumour could not be removed by myomectomy it was most improbable that pregnancy would occur and continue to full term. He advised early operation in all cases.—Dr. B. A. H. SOLOMONS said that during his term at the Rotunda Hospital he saw a good number of cases of women who became pregnant after myomectomy.—In reply, Sir WILLIAM SMYLY said that the discussion proved that they were not agreed on the question when to operate. He recognised the importance of preserving the power to bear children, and he believed that myomectomy would rather increase fertility.

Sir WILLIAM SMYLY read a paper on a case in which a Papyraceous Fœtus was Expelled before a Living Child. In January, 1911, the patient conceived, and though she twice threatened to abort she went to the end of the seventh month. She then expelled a papyraceous fœtus, but the placenta did not come away. Next day it was decided to divide the funis as high up in the cervix as possible in the hope of saving the second child. A septic fever ensuing she was removed to a nursing home, and the second child delivered by bipolar version. The placenta and membranes of this child, which died during the extraction, were expelled in about half-an-hour, and appeared to be fresh and normal, but as there was no sign of the other placenta following the hand was introduced, and it was found firmly adherent in the neighbourhood of the right cornu of the uterus. The patient made a good recovery.—Professor SMITH considered the cause of the fœtus becoming papyraceous was the insertion of placenta in the cornu of the uterus. The practical point appeared to him to be whether interruption was justified or not. So far as could be gathered the placenta of the papyraceous fœtus was not the cause of the trouble.—Sir WILLIAM SMYLY, in reply, said that he attached more importance to the pathological condition of the placental site than to its anatomical position. The fact that the papyraceous fœtus came first was the important feature of the case. The septic fever no doubt originated in the cord which was lying in the vagina for 24 hours before it was divided.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Jan. 5th, Dr. Preston King, the President, being in the chair.—The following cases and specimens were shown:—Dr. R. Waterhouse: A case of (probably arsenical) Pigmentation of the Trunk, Neck, and Shins in a woman aged 27. She had been an epileptic for 11 years and was very simple. For ten years she had taken bromides as an out-patient, and had 40, 50, or more fits every year. Eleven months ago she commenced to take drachm doses of syrupus ferri phosphatis co. three times a day in addition, and three weeks later 4 minims of Fowler's solution were added to the mixture. From this time to the present no fit occurred, but a week ago, on account of a complaint of abdominal pain and irritability of the bladder, an examination of the abdomen was made and pigmentation noticed. There was no keratosis of the palms or soles. The deep reflexes were markedly exaggerated and there was a tendency to ankle clonus, but the plantar reflexes were flexor in type. The friends had only noticed the darkening of the skin within the last year.—Dr. V. Wiley: A man, a French polisher by trade, suffering for the past 18 months from Occupation Neurosis. He complained of stiffness and numbness of the right hand and was unable, with his eyes closed, to distinguish the shape or name of objects placed in that hand—round objects he called square, &c. There was no wasting of muscles or trophic change; radial reflexes were lost on both sides.—Mr. H. G. Terry: Four Inches of Stem of an Ordinary Thermometer, made into the shape of a bi-coudé catheter. It was removed from the bladder of an old man who used it for sounding for stone. One day the portion shown broke off in the bladder whilst sounding, and it was not until three weeks after that, owing to severe pain, frequency of micturition, and hæmaturia, he applied for relief. It was removed by a suprapubic incision, being found surrounded by a large blood-clot.—Mr. A. de V. Blathwayt showed the lower half of the Spinal Column of a woman aged 29, who had drowned herself. Five years previously she fell out of a window and sustained a comminuted fracture of the twelfth dorsal and first lumbar vertebræ with some dislocation. There was complete paralysis below the lesion. Laminectomy was performed. After two years she was able to resume her occupation as servant, her only disability being prolapse of the uterus, which was improved by operation 12 months before death.—The President read notes of two cases of Treatment by Vaccines. The first case was that of a man aged 69, who had suffered for many years from a "skin disease." When first seen early in 1910 his whole body, including the arms, legs, and head, was a mass of ulcers in various stages of suppuration and healing, a few being mere scars and many covered with scabs. A pure culture of staphylococcus albus was obtained from the pus, and from this a vaccine was made and a 50,000,000 dose injected every four days; after three injections the dose was increased to 100,000,000, and after six injections there was marked improvement, and after the tenth injection the skin was quite clean and free from ulcers; three more injections were given. There was slight reaction after the first and less after the second, and none after the subsequent injections. Seen six months later he was still quite well. The second case was that of the President himself. For years he had suffered from bronchial catarrh and bronchitis, having had one or more yearly attacks which had laid him up for two or three weeks at a time. During an acute attack in October, 1910, a vaccine was prepared from the growth obtained from the sputum. The treatment was begun while the patient was still confined to bed with an evening temperature of 100° F. There was definite reaction, the temperature rising one degree the first night and less afterwards till eight or ten injections had been given. A 50,000,000 dose was used, and was given every fourth day and continued up to Christmas. The acute attack was cut short from the usual two or three weeks to six days, and since then there had been no further acute attacks down to January, 1911. During the last two winters he had suffered from slight colds which had aborted after a few days.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Jan. 16th, Dr. J. Mansell Moullin, the President, being in the chair.—Mr. J. D. Mortimer read a paper on the Need of Preparation for Anæsthesia. He pointed out that the choice of anæsthetic and of the position, the course of anæsthesia, and the after-condition were influenced, to an extent not always realised, by the presence of various general and local disorders—e.g., anæmia, obesity, oral sepsis—and that means should be taken to remedy them whenever there were time and opportunity. The value of preliminary injections of omnopon or morphine and atropine was mentioned in diminishing emotional and reflex disturbance, thus avoiding incidental risks and "saving" the anæsthetic. Although without personal experience of "delayed chloroform poisoning," he thought it well to test the urine for acetonuria in children and to regulate the diet and give glucose if found necessary. The difficulties and dangers attendant on a loaded stomach were described, and an emetic or lavage was recommended when possible in emergencies. Clearance of the bowels should be begun at least 36 hours before operation, thus giving time for it to be done effectually and avoiding disturbance during the last few hours preceding operation. If excessive it tended to post-operative nausea, atony, and exhaustion. Usually the last meal (a light one) should have been taken at least six

hours before anæsthesia, but simple drinks in moderation (not milk) might be allowed to within an hour, their refusal causing sometimes much discomfort. Frank and judicious explanation should be made to children, who were often alarmed by the presence and proceedings of the anæsthetist being entirely unexpected. — Mr. A. F. Penny read a paper on Acute Inflammation of the Middle Ear. In the early stages there was always some deafness. In these early stages harm was often done by amateur treatment, syringing, &c, fresh focuses of infection being superadded. Early treatment, however, was essential on account of the danger to life of chronic suppuration, the intense pain of the acute attack, and the liability to cause permanent deafness. When it became chronic a radical mastoid operation was often desirable. All cases except those of tubercular origin commenced in the naso-pharynx. Scarlet fever was a fruitful cause, as was also influenza, the latter being especially liable to be followed by meningeal complications. Chronic nasal obstruction was also a very important factor. When pus had formed the membrana tympani should be perforated to enable it to escape. In the earlier stages it was important that the Eustachian tube should be kept patent. If the mastoid antrum became infected it should at once be opened. When this extended and the condition known as Bezold's mastoiditis took place an extensive removal of the bone was often necessary, on account chiefly of the danger of extension of the infection to the lateral sinus and consequent pyæmia. Acute otitis might also involve the labyrinth. If, however, there was no spontaneous nystagmus except in extreme positions of the eyes, nor by rapid head movements, absence of the "fistula" symptom and presence of the caloric reaction, any suppurative infection of the labyrinth, as well as any severe disease of the vestibular apparatus, might be excluded. Such infection from the middle to the internal ear, when it did occur, usually travelled either through the external semicircular canal, through the promontory, or through the fenestra ovalis. The various operations on the labyrinth and cochlea were described in detail.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held in the Royal Victoria Infirmary, Newcastle-on-Tyne, on Jan. 18th, Mr. A. Angus Martin, the President, being in the chair.—Dr. Robert Hutchison opened a discussion on Rickets. He reviewed very shortly what little there is of the pathology, and the clinical types were briefly dealt with as being known to all. To the etiology and treatment he referred more particularly. He dismissed in a word such exploded theories of etiology as congenital syphilis, dilatation of the stomach, microbic infection, intestinal intoxication, absence or defect of internal secretion, and trophic or nervous influences. He considered more fully the lime and acid theories and ultimately dismissed them also. Finally, while acknowledging the undoubted though accessory importance of the general hygienic conditions, he ascribed the disease to erroneous feeding, *the only cause*. For confirmation of this view he turned to clinical experience and the assistance to be gained from the effects of treatment. Little doubt could be entertained that deficiency of fat was the chief factor, but he did not negative the possibility of deficiency of protein and phosphorus acting as an adjunct to it. In reference to treatment, this was mainly dietetic. By way of prophylaxis, the chief faults to be avoided were (1) too prolonged breast-feeding, and (2) in bottle-fed children, too dilute a mixture being used. Increase in the amount of fat administered was the most important measure to be adopted—e.g., cod liver oil, or cotton oil, which was as good, supplemented by phosphorus and iron. He considered diarrhœa no bar to the administration of fat, as was formerly thought. An animated discussion followed, to which Dr. Hutchison replied.—The President expressed the appreciation of all present of the address, which had been eloquent and instructive, and, considering the familiar nature of the disease, refreshing.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 10th, Dr. F. H. Jacob, the President, being in the chair.—Professor G. Sims Woodhead delivered an address on the Laboratory and Clinical Work. He confined his remarks chiefly to the recent work on body temperature and electro-cardiograms. He pointed out the great advantage to clinical medicine in having a continuous temperature chart for the whole 24 hours in such diseases as tuberculosis. It was the late Dr. Gamgee who initiated the taking of continuous temperature records by means of thermo-electrical methods. Professor Woodhead continued his work chiefly in connexion with investigating the effects of alcohol on the body temperature. The initial work was enormous, and it took eight or nine months before he obtained his first satisfactory record. After that, however, the work became comparatively easy. Professor Woodhead then explained in detail the photographic temperature recorder of Dr. Gamgee and also the "thread recorder." By means of arrangements with the National Telephone Company a continuous temperature of a patient in Addenbrooke's Hospital, Cambridge, was automatically recorded in the University laboratory. The lecturer then stated that small doses of alcohol raised the surface temperature but lowered the rectal temperature. Food lowered the surface temperature, but if accompanied by warm fluid the temperature was raised. Hot fluids immediately raised the rectal temperature, but only for a short while. It was possible in the future that all hospital patients could have continuous temperature records taken, and this should be of great value in enabling them thoroughly to study the progress of disease. Professor Woodhead explained the principles of taking an electro-cardiogram, and the details of the machine used. Lantern slides were shown to illustrate his remarks. He said that electro-cardiograms were almost as characteristic of individuals as were finger-prints, so much so that any variation in an individual's electro-cardiogram meant that there was some lesion of the heart. In Addenbrooke's Hospital a record was now taken of every case of heart disease, and it was hoped that in time these might, by comparison with future post-mortem examinations, lead to much usefulness.—Dr. A. Fulton, in proposing a vote of thanks, wondered whether the taking of continuous temperature records and cardiograms would be part of the duties of an Insurance doctor, and drew a vivid picture of the tired general practitioner being awakened in the night by the sudden flash of the galvanometer mirror on the ceiling telling him that a patient a mile away had had a sudden rise of temperature.—Dr. P. Boobbyer seconded the vote of thanks.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 11th, Dr. P. S. Abraham, the President, being in the chair.—Dr. David Walsh showed: 1. A young woman with Recurrent Rosacea and Cardiac Disease, to illustrate further his views that chronic dermatoses were prone to be kept up by cardiac disorders, apart from circulatory disturbances. 2. A case of Alopecia of the band form in a woman, associated with seborrhœa of the scalp. A curious feature of this case was the presence of a sclerosed thyroidea ima artery.—Dr. G. Norman Meachen showed: 1. A man, aged 40, with Epithelioma supervening upon Lupus Vulgaris that had been treated by X rays. A considerable amount of destruction of the tissues of the upper lip and nose had occurred, the patient's life being rendered intolerable by the inability to retain saliva, &c. Radium treatment was now contemplated in view of the fact that a plastic surgical operation did not appear promising. 2. A case of Psoriasis with Chronic Facial Œdema in a young woman aged 30, the areas of œdema below the eyes and the thickening of the tissues of the upper lip having appeared almost coincidently with the cutaneous eruption seven years ago. Some of her symptoms suggested a myxœdematous condition, but no improvement had occurred under the administration of thyroid extract.—Dr. Tom Robinson showed a man with a Lichenoid Eruption, chiefly upon the legs and arms. The papules were mostly of the follicular type and the irritation had been severe.

BRADFORD MEDICO-CHIRURGICAL SOCIETY AND BRADFORD DIVISION OF THE BRITISH MEDICAL ASSOCIATION.—A joint meeting was held on Jan. 16th.—The following specimens and cases were shown:—Professor H. J. Campbell: A case of Sprue.—Dr. C. F. M. Althorp: (1) A patient after operation for Cancer of the Rectum; and (2) specimens from a case of Acromegaly.—Dr. R. Honeyburne: (1) Microscopical specimens from Dr. Althorp's case of Acromegaly; and (2) microscopical specimens from a case of Acute Pancreatitis.—Mr. Basil Hughes: (1) Two cases of Cellulitis of the Palm treated by Autogenous

Vaccines; (2) cases of Injury to the Elbow; (3) a case of Gonococcal Arthritis of the Wrist-Joint treated by Vaccine; (4) two cases of traumatic Myositis Ossificans; and (5) a case of Sycosis treated by vaccines.—Mr. J. Basil Hall: (1) Lantern slides of Surgical Cases; (2) Osteo-sclerosis of the Tibia from a case of Gangrene of the Leg; (3) Carcinoma of the Rectum; (4) Endothelioma of the Head of the Tibia; (5) Cystic Tumours in connexion with (*a*) Appendix, and (*b*) Rectus Abdominis; (6) Hypernephroma; and (7) Carcinoma of the Body of the Uterus.—Dr. T. Jason Wood: (1) A case after operation for Ectopia Vesicæ; (2) a case after Suture of the Patella for Fracture; (3) specimen of Cancer of Trachea and Œsophagus; (4) Epithelioma of Skin over the Elbow-joint; and (5) Advanced Carcinoma Mammæ.—Dr. A. F. Martin: (1) Specimen of a Large Nasal Polypus; and (2) specimen of an Early Ovum.—Mr. F. W. Goyder: (1) Lantern slides of Congenital Dislocation of the Hip before and after Reduction by the Lorenz Method; (2) lantern slides of cases of Hare-lip and Cleft Palate; (3) photograph of a case of Epispadias; and (4) Carcinoma of Colon removed from a woman aged 32 years.—Mr. P. McEwan: Uterine Fibroid.

Reviews and Notices of Books.

A Manual of Bacteriology, Clinical and Applied. By R. TANNER HEWLETT, M.D. Lond., F.R.C.P. Lond., D.P.H., Professor of Bacteriology in the University of London; Director of the Public Health Department, King's College, London; Director of Pathology, Seamen's Hospital, Greenwich; Lecturer on Bacteriology, London School of Tropical Medicine. Fourth edition. London: J. and A. Churchill. 1911. Pp. 703. Price 10*s.* 6*d.* net.

Professor Hewlett's work has long been a favourite text-book of bacteriology amongst medical students and practitioners. That it has lost none of its popularity is indicated by the appearance of a new edition after so short a period as three years. As we have noticed each successive edition at some length it is unnecessary now to enter into any detailed criticism, for in appearance, arrangement, and treatment of the subject the book is practically unchanged, and it still possesses those valuable characteristics—due to the fact that the author, though a bacteriologist, does not forget that he is also a physician—which make it so suitable for the medical man.

The fourth edition is enlarged by about 75 pages—a very moderate addition considering the amount of new work to be incorporated. It has also been largely rewritten and added to. The plates, always an important feature of the work, have been slightly increased in number and in several cases improved. This is the case with the representations of S. aureus in pus, the meningococcus, the B. diphtheriæ, the B. typhosus, and the treponema pallidum. Professor Hewlett has carried on the work of Dr. Allan Macfadyen on endotoxins, and some of the most important additions in this volume concern the properties, method of extraction, and therapeutic use of these puzzling and little understood bodies. For prophylactic use a vaccine consisting of diphtheria endotoxin is said to possess all the advantages and none of the dangers of antitoxic serum. A new section on anaphylaxis serves chiefly to show how scanty at the present time is our knowledge of this condition. The description of the tuberculins has been rewritten, and "bacillary emulsion" is now included. There is a fuller description than formerly of the mode of entrance into the body of the tubercle bacillus, and of its relationship with food; while among the clinical tests for tuberculosis Emery's method, based on the fixation of complement, is described at length, as are also the more modern methods for the demonstration of the bacillus in sputum.

Recent work on the leprosy bacillus finds a place, as does also Bordet's work on the bacillus of whooping-cough, and a description of the B. botulinus. Amongst the pathogenic blastomycetes there is an account of sporotrichosis and its organism, and of the organism of thrush, which was formerly grouped with the hyphomycetes. The section on the protozoa has been altered, and the various spirochætæ, together with the treponema pallidum, are treated in this group; there is also additional information on the trypanosoma gambiense. Infantile paralysis, typhus fever, and phlebotomus fever appear for the first time in this edition. The book concludes, as before, with the useful and practical section on disinfection, and on the bacteriology and bacteriological examination of water and milk. This section has been revised.

The book is well and clearly printed, and of good appearance. It will, no doubt, continue to be a favourite manual for students, practitioners, and medical officers of health.

Heart Sounds and Murmurs: their Causation and Recognition. By E. M. BROCKBANK, M.D. Vict., F.R.C.P. Lond., Senior Honorary Assistant Physician, Royal Infirmary, Manchester. London: H. K. Lewis. 1911. Pp. 56. Price 2*s.* 6*d.*

THIS volume sets out simply, clearly, and in convenient pocket-book form for clinical reference the elements of cardiac auscultation, and we believe that students will obtain much information by referring to the work during their attendance in the out-patient rooms and wards. The description of the various alterations that may occur in the sounds of the heart is so clear and accurate that, when a student hears a murmur or modification of the heart sounds, on referring to Dr. Brockbank's remarks he will without difficulty find the explanation thereof.

The theoretical considerations of the production of the heart sounds and the physical conditions required to produce murmurs or reduplication of the heart sounds are also well dealt with. In discussing the causation of the crescendo murmur heard over the apex of the heart and associated with mitral stenosis, Dr. Brockbank adopts the view that it is produced at an orifice which closes whilst a murmur is being produced at the orifice. He submits that the mitral valve, when stenosed, is often so diseased that it cannot close at all during ventricular systole, or only at a late phase of ventricular systole when a sufficient amount of force has been developed to bring together the stiffened edges of the valve. Whilst this force is gathering, blood regurgitates through the patent and diseased valve, producing a systolic murmur, to which a rising pitch character is imparted by the closing of the valve. The crescendo murmur, therefore, being early ventricular systolic or presphygmic in rhythm, occurs immediately before the carotid pulse. The view that the crescendo murmur of mitral stenosis is ventricular systolic and not auricular systolic is, we believe, gradually gaining ground, but it is not as yet generally adopted.

The remarks on cardiac hæmic murmurs are also worthy of attention. Dr. Brockbank doubts the suggestion that has been raised as to their causation—namely, that they are due to diminished viscosity of the blood. He points out that in chlorosis, in which these murmurs commonly occur, there is sometimes two or three times the normal volume of blood present, and this may lead to abnormal distension of cavities, and so to the easier production of fluid veins, especially at the semilunar valve orifices. Many theories have been put forward as to the origin of hæmic murmurs, but the one advanced by Dr. Brockbank brings the causation of such murmurs more into accord with the physics of organic murmurs.

We can recommend this volume as a useful addition to the student's library.

Allgemeine und Spezielle Pathologie des Zwerchfels. Von Privat-docent Dr. HANS EPPINGER in Wien. With 31 illustrations in the text. Wien und Leipzig: Alfred Holder. 1911. Pp. 266. Price 6.50 marks.

THIS is a special section of the supplement of Nothnagel's well-known Pathology and Treatment. It is probably the largest monograph that has ever been devoted to the diaphragm, and yet when the book is read it is seen that there is evidently much to be said about this important organ. The author has dealt in separate chapters with the anatomy, the histology, and the development of the diaphragm; then he has considered its physiology, first as a part of the respiratory apparatus, and secondly, as assisting the circulation; and finally, the action of the phrenic nerve has been studied. A careful account is then given of the various positions assumed by the diaphragm in inspiration and expiration, and the results of the examination of 106 men and of 70 women are given showing the highest point reached on both the right and the left side.

An account follows of the general pathology of the diaphragm. The special pathology also receives due attention, and nearly 70 pages are devoted to the subject of diaphragmatic hernia, of which many varieties are described. The prognosis and treatment of this condition are also considered. Various other affections of the diaphragm are dealt with, and the only other important lesion, subphrenic abscess, receives full treatment. The author divides the forms of this abscess into right and left anterior intraperitoneal abscess, and right and left posterior intraperitoneal abscess, and right and left extraperitoneal abscess. The diagnosis, prognosis, and treatment of this condition are discussed. A very useful table is supplied in which the results are given of a large number of cases classified according to the point of origin of the suppuration. The cases are further divided into those which were treated by operation and those which were not. Although there were in all more than 300 cases in these series the numbers are hardly large enough to give exact indications as to the prognosis in the several classes. The most fatal cases appear to be those arising from perforation of the duodenum, of which there were six in all; four of these were operated on and two were not, but all died. The numbers are clearly too small to justify the conclusion that a subdiaphragmatic abscess arising from such a cause must necessarily end fatally. The final section deals with the nervous affections of the diaphragm, such as paralysis and spasm. A bibliography containing some 4000 items—not the least valuable portion of a carefully written and complete work—is supplied.

The Blood and its Third Anatomical Element: Application of the Microzymian Theory of the Living Organisation to the Study of the Anatomical and Chemical Constitution of the Blood and to that of the Anatomical and Physiological Causes of the Phenomena of its Coagulation and of its other Spontaneous Changes. By A. BÉCHAMP, formerly Professor in the Medical Faculty of Montpelier (France). Translated from the French by MONTAGUE R. LEVERSON, M.D., of the Baltimore Medical School, and M.A. and Ph.D. of the University of Göttingen. Philadelphia: Boericke and Tafel. 1911. Pp. 438. Price, cloth, $1.50.

IN this translation of part of the work of Béchamp there are the translator's preface, a post scriptum, an author's preface of 84 pages, and a "Preliminary" before a chapter entitled "Introductory and Historical" is reached. The translator predicts that the nineteenth century will come to be known by the name of Béchamp, "as are the centuries of Copernicus, of Galileo, and of Newton by their several names." Indeed, the translator greets him as the Master (in distinct type), who was in his eighty-fifth year at the time of the publication of the work before us. We should add that M. Béchamp died in 1908. "A collection of molecular granulations Béchamp named microzymas," and these "*evolved* into *bacteria*." "The word microbe must be erased from the language of science," while the "Microbian Theory of Disease" was declared by the *Master* to be the "greatest scientific silliness of the age." This work is said to be the crown to Béchamp's work upon ferments, &c. M. Pasteur is accused of plagiarism who in 1872 attempted his "boldest plagiarism." The author asserts that the microzymian theory is to biology what the Lavoisierian theory of matter is to chemistry.

A few further quotations will show better than comment can the views of the author. "Normal air never contains morbid microzymas, what used to be called germs of disease and now microbes," and it is maintained that "*diseases are born of us and in us.*" In the chapter on the blood and its third anatomical element, the reader must remember that this third element has nothing to do with what are called platelets. It consists "of a microzyma enveloped in an atmosphere of a special albuminoid substance, insoluble in the sanguineous medium" (p. 215). The translator adds a note on p. 229, on the blood of chameleons, in which he makes the mistake of confusing these animals with camels as regards their blood corpuscles. The three anatomical elements of the blood "become vibrionious by individual evolution," which statement, the author remarks, "was a novelty for physiology and even for chemists." No doubt it was. "The fibrin of the blood is a false membrane containing microzymas, whereof the intermicrozymian gangue is a specialised albuminoid substance. ..... It is owing to its microzymas that fibrin liquefies starch of amidon. ..... The microzymas of fibrin in liquefied starch undergo vibrionian evolution notwithstanding the presence of creosote."

We have said enough to enable the reader to judge as to the author's views. We need hardly refer to what is called a "Postface," and it is scarcely worth while to point out such little shortcomings as "quarternaries," "literateurs," "Louget," "Miathe," "Milné-Edwards," "noither," "Captions of the following chapters." What is to be said of "extalytic contact" and of "gangue"? On p. 420 we find, "The world has yet to learn how much it owes to this remarkable genius [i.e., M. Béchamp]. The acknowledgment will be resisted by all those interests which fatten upon ignorance and trusting confidence of the people." In the words of the translator's ending to his own preface, "*Ainsi soit-il.*"

Experimental Pedagogy and the Psychology of the Child. By Dr. ED. CLAPARÈDE, Professor of Experimental Psychology at the University of Geneva. Translated by MARY LOUCH and HENRY HOLMAN. London: Edward Arnold. 1911. Pp. 332. Price 5*s.* net.

Dr. Claparède explains in his preface that this work is not to be considered as a manual of pædagogy but as a guide to the study of psychological science and to the psychology of the child. The work is somewhat alarming at first sight. Methods of education have changed so rapidly since the middle of the last century that, as in all great upheavals, excesses have arisen, and the views of the extremely modern "educationist" are not very unlike those so amusingly satirised by Mr. Calderon in "Downy V. Green," where he describes the educational system of Dr. MacGuffin, of Goober Valley, with his science of "Mindahlogy."

But though we have called Dr. Claparède's book alarming at first sight, it is only because it contains so many new terms; the matter of the book is really fairly simple, that is to say if such a complicated subject as education can ever be considered simple. After a historical sketch of the work done in the observation of the mental development of the

child, he states the problems to be considered. Methods of research are next described, and the two following chapters, which conclude the book, are devoted to mental development and intellectual fatigue. Dr. Claparède's definition of experimental pædagogy is this: "The knowledge of, or the inquiry into, the circumstances favourable to the development of the child, and the means of educating him towards a given end"; and, if we have gathered his meaning rightly, his position is set out on p. 204 as follows: "The child develops naturally by passing through a certain number of stages, which succeed each other in a constant order. Each stage corresponds to the development of a certain function or aptitude, and the play connected with each of these gives pleasure to the child. All objects susceptible of bringing into play this new-born function or aptitude naturally interest the child, captivate him and attract him, while those which do not correspond to the play of any existing aptitude leave him indifferent or are instinctively repugnant to him. The secret of pedagogy consists in making use of those natural aptitudes of the child, instead of reprimanding him because of those which he lacks—those with which he may not be endowed, or which he does not yet possess." In other words, education should not mean filling the scholar with facts which have little or no meaning for him, but rather the bringing out of the potentiality for knowledge that he possesses.

Dr. Claparède's work may be cordially recommended to all teachers who wish to obtain a general view of the ideals at which they should aim.

Pathological Technique: A Practical Manual for Workers in Pathological Histology and Bacteriology, including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By FRANK BURR MALLORY, A.M., M.D., Associate Professor of Pathology, Harvard University Medical School; Pathologist to the Boston City Hospital; and JAMES HOMER WRIGHT, A.M., M.D., S.D., Director of the Pathological Laboratory of the Massachusetts General Hospital, Assistant Professor of Pathology, Harvard University Medical School. Fifth edition, revised and enlarged, with 162 Illustrations. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 507. Price 13*s.* net.

THE appearance of a fifth edition may be regarded as sufficient evidence of the popularity and practical utility of any work. In general appearance this volume does not differ from its immediate predecessors, the arrangement of the subject matter under three main headings remaining unaltered. Nevertheless, the entire text has undergone a thorough revision—most obvious, perhaps, in the third section, to which nearly 40 pages of new matter have been added.

The first section, dealing with post-mortem examinations, is clearly written, and the instructions given are ample, though we should have welcomed a section on the art of removing various viscera through natural orifices—knowledge frequently demanded of the general practitioner, at least on this side of the Atlantic, where permission is granted only for what may be termed a "limited p.m." We hope that in a future edition this practical want will be supplied.

The second section, Bacteriological Methods, has at first sight undergone but little change, still there are changes and additions here also. Methods now obsolete, such as "roll cultures," have been eliminated, and alternative methods are described for the preparation of nutrient media, but we shall expect to find in the next edition that the authors will pin their faith to the exact methods of nitration and standardisation that are now matters of routine in the well-organised bacteriological laboratory. Rather more than 100 pages are devoted to the chief microscopical and cultural characters of the pathogenic bacteria, with brief accounts of their association with, and diagnosis in, pathological lesions, and their pathogenesis for laboratory animals. This section is, in the main, clear and accurate, although upon some minor points we should certainly join issue with the authors, as, for example, that the very brief original staining times in each of the solutions are alone given under Neisser's method (for B. diphtheriæ), adherence to which would undoubtedly result in complete failure in the majority of instances. The microphotographs are usually excellent, but some few, where the magnification to 2000 appears to have been attained by the enlargement of the negative and consequent loss of detail, are unfamiliar and therefore unconvincing. New matter in this section includes the antiformin methods for the detection and isolation of bacillus tuberculosis, and the bacteriological diagnosis of cholera according to McLaughlin's excellent directions. We note, however, as before, the absence of the agglutination and sedimentation methods in the diagnosis of infections due to bacillus mallei.

The new matter occurs largely in the third section, and comprises a concise summary of the recent work in the diagnosis of syphilis and the methods of preparing bacterial vaccines. The treponema pallidum is carefully described, together with various tried and proved staining methods, but culture methods are not even referred to. Complement fixation methods, both Noguchi's modification and Wassermann's original method, are well described, but with a distinct preference for the former. Perhaps the most useful pages in this section are those describing practical workaday methods for standardising the various reagents employed in these tests, such as antigen and hæmolysin. Other important additions are Alzheimer's ingenious method for the quantitative differential count of the cells in cerebro-spinal fluid; a differential table of entamœbæ and cultivation methods for amœbæ; and a description of the Negri bodies in rabies, this being accompanied by an excellent photograph.

By sound revision this volume fully maintains the high standard of the earlier editions, and not even the clinical pathologist who already possesses one of the earlier editions can afford to neglect the present one.

Die Palpablen Gebilde des Normalen Menschlichen Körpers und deren Methodische Palpation: nach eigenen Untersuchungen an der Leiche und am Lebenden. By Dr. TOBY COHN, Nervenarzt in Berlin. Part III.: *Neck and Head.* Berlin: S. Karger. 1911. Pp. 377-586. Price 8 marks.

THE third part of this work on the structural details of the body recognisable by touch deals in a most elaborate fashion with the head and neck, with the description of which more than 200 pages are occupied. The extraordinarily painstaking nature of the task will strike the reader at once as he turns over the pages of this section, and he may perhaps question the wisdom of the devotion to minutiæ that the author betrays. Where so many facts are aggregated, some indication of relative significance or insignificance would have been of service. From the nature of the subject there is to be found in this part a great deal of anthropological information on the shape and type of skull, on hair, eyes, ears, nose, and so on. The author mentions various departures from the normal in the case of the formation of the pinna, for instance, but if this is to be done at all, it might have been done more completely. More than one well-recognised degenerate ear is not referred to. The philtrum is mentioned, but there is no note of the interesting variations in its shape that may occur. As a whole, the section is a valuable contribution to the important and not sufficiently taught subject of surface anatomy. The time is well spent that is devoted to the study of the landmarks of the human

frame as they reveal themselves to the educated finger. With Dr. Cohn's admirable text-book as a guide the student will acquire an immense amount of useful information which will stand him in good stead.

LIBRARY TABLE.

Outlines of Early Development. By R. W. JOHNSTONE, M.A., M.D. Edin., F.R.C.S. Edin., M.R.C.P. Edin. With a preface by Sir J. HALLIDAY CROOM. Edinburgh: John Currie. 1911. Pp. 23. Price 1*s.* 6*d.* net.—This sketch of the early life-history of the ovum has been written to supply the students in the class of obstetrics in the University of Edinburgh with a simple and connected outline of the facts of embryology, essential to a good understanding of the science of midwifery. Dr. Johnstone has elaborated the matter of the lectures, and this little book contains a clear, if somewhat condensed and dogmatic, account of the main facts of the early development of the human ovum. For the sake of simplicity, the numerous questions of comparative embryology that must be considered if this subject is to be treated in any detail have been omitted. This *résumé* of the subject should prove useful to the students for whom it is intended.

Descriptive Catalogue of the Specimens Illustrating Gynæcology and Obstetrics in the Museum of University College Hospital, London. Second edition. By HERBERT R. SPENCER, M.D., B.S. Lond., F.R.C.P. Lond., Professor of Obstetrics and Gynæcology and Obstetric Physician to University College Hospital; and T. W. P. LAWRENCE, M.B. Lond., F.R.C.S. Eng., Pathologist to the Hospital and Curator of the Museum. 1911. Pp. 213. Price 2*s.*—The collection of specimens in the obstetrical and gynæcological sections of the Pathological Museum of University College Hospital Medical School is a particularly good one, and the number described in this catalogue is evidence of this fact. We would draw attention more especially to the series of fibromyomata of the uterus, which are very remarkable, and the large series of specimens of cancer of the uterus. The second edition of the catalogue follows the lines of the first, written by Sir John Williams and Mr. C. Stonham, but the size of the work is much increased, and the introductory notes to each section have been considerably amplified by Dr. Spencer. In its present form this catalogue is an excellent example of what such a book should be, and the authors are to be congratulated on the excellence of their work, and more especially on the richness of the collection of specimens, the descriptions of which make up the bulk of the book.

Aids to Histology. By ALEXANDER GOODALL, M.D. Edin., F.R.C.P. Edin., Lecturer on Physiology, School of Medicine of the Royal Colleges, Examiner in Physiology to the Royal College of Physicians, Edinburgh. London: Baillière, Tindall, and Cox. 1912. Pp. 135. Price, paper, 2*s.*; cloth, 2*s.* 6*d.* net.—This is a new addition to the well-known Students' Aid Series. It is not a laboratory handbook, in the ordinary sense of the word, but rather a brief manual of descriptive minute anatomy for the junior student, who is prone to be only confused by too lengthy descriptions. The senior student also may possibly find it useful in the course of the revision of his work before examination. It is not intended to supplant laboratory work, and provided it is used in the spirit in which it is written it may be of service. What to observe and what to do are here explained; how to observe and do them must be learnt by actual laboratory practice, and can be learnt in no other way.

Famous Chemists. By E. ROBERTS, B.Sc. Lond. London: George Allen and Co., Limited. 1911. Pp. 247. Price 2*s.* 6*d.*—This is a disappointing book; the 26 biographies contained in it are scrappy, and at least in one instance one of the most important events in the career of a great chemist is omitted altogether. The author has forgotten to record that amongst Cavendish's remarkable achievements was the "sparking" of air until it was reduced to a small unoxidisable residue. This residue was the argon discovered by Lord Rayleigh and Sir William Ramsay in 1894. "If there is any part," wrote Cavendish in 1785, "of the phlogisticated air of our atmosphere which differs from the rest and cannot be reduced to nitrous acid we may safely conclude that it is not more than 1/120th part of the whole." Was not Kekulé, also—the famous originator of the benzene hexagon nucleus theory—at one time in the laboratory of St. Bartholomew's Hospital, under the directorship of Dr. Stenhouse? We can find no mention of it, although it is interesting to be reminded that this great chemist spent some of his time, and gained some of his ideas, in the laboratory of a London hospital. It is notable that amongst the "famous chemists," 26 in all, seven of them approached chemical questions through their early medical studies. The data as to the birth, marriage, and death of the "famous chemists" are, of course, useful, but the chief points in the history of their career are capable of much more interesting treatment than is here given.

MISCELLANEOUS VOLUMES.

IN our issue of March 11th, 1911, we commented on the first edition of *Essays on Duty and Discipline, a Series of Papers on the Training of Children in Relation to Social and National Welfare.* We are glad to welcome the present enlarged and improved reprint of these essays. (London, New York, Toronto, and Melbourne: Cassell and Co., Limited. Price 3*s.* net.) The addition of ten new ones raises the total number to 40. The new essays are contributed respectively by Lady Laura Ridding, Sir R. Baden-Powell, Mrs. Claude Epps, B.Sc., the Hon. George H. Martin, Litt.D., the Right Rev. Edgar Jacob (Bishop of St. Albans), Dr. Bernard Myers, the Rev. J. R. Miller, D.D., Isabel D. Marris, the Rev. Ernest R. Hull, S.J., and Lord Roberts. There can be little doubt that the disquieting condition to which the papers are designed to compel startled attention—viz., "to the very generally acknowledged growth of indiscipline amongst British children of all classes, to the decay among them of a sense of duty, and to the apparent gradual disappearance of the ancient British determination to overcome difficulties by the force of a strong will, which declined under all circumstances to recognise even the possibility of defeat"—is a threatening national danger. This timely publication should deeply interest and influence everyone connected with the upbringing of the young.——If it should happen that any medical man contemplates sending his son into the Royal Navy, he will find considerable assistance in the revised edition (1911) of *How to Become a Naval Officer* (London: Gieve, Matthews, and Seagrove, Limited). Admiral Fremantle gives it the benediction of his introduction. It consists of four parts, dealing respectively with the Admiralty Regulations, descriptive accounts of the first two years of the course (which are spent at Osborne), and the last two years (which are spent at Dartmouth), and the training of naval officers after the school period. An appendix describes the necessary physical requirements for a commission in the navy and gives a list of the articles required for a cadet. Many illustrations of the two colleges and their various departments accompany the book.——*Sexual Disease and its Medical Prevention.* By H. N. ROBSON, M.R.C.S. Eng., L.R.C.P. Lond. (London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Price 3*s.* 6*d.* net) is now in its third edition. The second edition was reviewed in THE LANCET of June 4th, 1910. In the present edition the word "sexual" replaces in the title the "social"

of previous editions. We learn from the preface that "since the second edition was issued two American warships, the *Concord* and the *Raleigh*, went from Manila to New York viâ the Suez Canal, visiting various ports *en route*. The crews were placed under the preventive measures described in these pages, with the result that they arrived home with a clean bill of health as far as venereal disease was concerned."

Arosa is in the Grisons, some 6000 feet up on the Rhætian Alps, and after glancing through *Where the World Ends*, by A. A. H. (Herr Junginger-Hefti, Bookseller, Arosa, Switzerland. 1911. Price 3*s.* post free), we should imagine it is one of the jolliest little villages in the world, better in winter than at any other time except it be summer. This book tells all about Arosa, its sports and amusements, its people and places, its advantages as a health resort for various lung and nervous troubles, who should visit it and who avoid it, how to get there and what to do when there. We do not see anything about how to get back, but we can well imagine, if all that is said in the book is as true as it is interestingly told and charmingly depicted in the illustrations, that no one ever wants to come back.

——It is highly probable that, as Dr. Frederick W. Saunders says in his *Stepping Stones to Health on the Nile* (London: H. K. Lewis. 1911. Price 1*s.*), the peculiarities of the climate of Upper Egypt are little recognised by those who recommend their patients to go there for the winter. While it is suitable for many conditions requiring a warm, dry climate, cases of valvular heart disease, pulmonary tuberculosis (except in an early stage), chronic gastro-intestinal catarrh, and persons of advanced age or low vitality should not be sent at all. In this little pamphlet Dr. Saunders gives a brief description of Assouan, Helouan, and Luxor, intermixed with many notes on transport (he particularly advises the all-sea route out), amusements, wraps, water, milk, dust, flies, chills, clothing, and what not, likely to be of use to those intending to go there.

In a leading article on Medical Internationalism in THE LANCET of April 30th, 1910, we commented on a pamphlet with that title presented by Dr. P. H. Eijkman, a physician at The Hague, to a meeting there of the Bureau of the Permanent Commission of the International Medical Congresses, on behalf of the Bureau Préliminaire de la Fondation pour l'Internationalisme, a society which keeps records of the associations, unions, leagues, conferences, exhibitions, and congresses of every nation, with a view to "organising the organisations." The Bureau has recently issued a further work by Dr. Eijkman entitled *L'Internationalisme Scientifique* (*Sciences Pures et Lettres*). It is proposed, following the example of the Bureau of the Permanent Commission of the International Medical Congresses, the Permanent Bureau of the Pharmaceutical Federation, and the Permanent Bureau of the International Institute of Statistics, which have their seats at The Hague, to establish there a Permanent International Bureau of Pure Sciences and Letters. In a preface Professor Paul S. Reinsch, of Berlin, Roosevelt Exchange Professor at the University of Wisconsin, U.S.A., makes the important observation that this organisation of organisations is not the outcome of any purposive struggle towards internationalism, but a simple and natural consequence of the tendency in each branch of science to follow the most practical and efficacious path. In the introduction Dr. Eijkman adds a few pages of supplementary matter to his former pamphlet on "Medical Internationalism," enumerating many additional international medical or quasi-medical bodies omitted from his list in the beforementioned pamphlet. He lays special stress on the fact that in the domain of hygiene the organisations are not exclusively composed of medical men, and consequently cannot be included in the Bureau of International Medical Congresses. He suggests, therefore, a permanent Commission of International Congresses of Hygiene and Demography, to bring together all the various bodies occupied with that special department of knowledge.

JOURNALS AND MAGAZINES.

The Kala-azar Bulletin, Vol. I., No. 1.—In THE LANCET of Dec. 16th we drew attention to the issue of an "introductory" number of a new bulletin which was to be devoted to the furthering of the study of kala-azar. That preliminary number consisted entirely of a list of some 900 references to works on the diseases caused by leishmania. The present publication is the real first number of the *Kala-azar Bulletin*, which is issued under the direction of the managing committee of the Sleeping Sickness Bureau, and under the editorship of Dr. C. M. Wenyon. In contains some extremely interesting editorial articles, the first of which relates to Experimental Kala-azar in Animals, giving details of recent investigations undertaken in Tunis, Paris, Italy, the Sudan, and India. The next contribution is on Spontaneous Canine Leishmaniasis, mention being made of the discovery of the disease by Basile in Bordonaro near Messina, by Critien in Malta, by Alvares and Pereira Da Silva in Lisbon, by Cardamatis in Athens, by Dschunkowsky and Luhs in Transcaucasia; and by Bousfield (very probably) in the Sudan. Allusion is also made to the negative results obtained by Donovan in Madras, by Fülleborn in Hamburg, and by Wenyon in Bagdad. An article full of interest on Experiments on the Transmission of Kala-azar by Blood-sucking Arthropods follows, and in it are discussed the investigations of Patton, Marshall, Basile, Sangiorgi, Gabbi, Franchini, and others. The remaining contributions relate to experimental work on oriental sore, the culture of Leishmania tropica, and to dermal leishmaniasis in Egypt and the Sudan, and in the Niger Territory. The number concludes with a bibliography containing a list of 60 references, being a continuation of the 900 already published in the "introductory" issue of the *Bulletin* to which we have previously made allusion. It will thus be seen that there is no lack of material on the subject of leishmaniasis. The *Kala-azar Bulletin* will, in our opinion, serve a very useful purpose in focusing the knowledge collected and by recording the results of researches made on leishmaniasis at home and abroad. The subject is becoming one of increasing importance in view of the fact that the distribution of the various forms of disease due to leishmania is now known to be far wider than was at one time believed. We wish our new contemporary all possible success in the work which it has so successfully begun in its first number.

The British Journal of Inebriety. Vol. IX., No. 3. January, 1912.—The first place in the January number of this journal is naturally given to the Norman Kerr Memorial Lecture on the Action of Alcohol on Body Temperature and the Heart, delivered at Cambridge by Professor G. Sims Woodhead last November. This important contribution to the scientific literature of alcoholism was summarised in an annotation in THE LANCET of Nov. 25th, 1911, p. 1497. The journal also contains an interesting article by Dr. Isador Coriat on the Psycho-pathology and Treatment of Alcoholism. Dr. Coriat discusses those cases of inebriety characterised by periodic drinking in which the periodicity is due to variations in the organism arising independently of environmental influences. As clinical types of this sort of inebriety he distinguishes: (*a*) periodic drinking due to slight depression and anxiety, such, for instance, as may be observed as a premenstrual

condition of women; (*b*) periodic drinking as an epileptic equivalent, or, in other words, the genuine dipsomanias; (*c*) periodic drinking due to certain recurring variations of mood which are closely related to, and in many cases identical with, the cyclic changes of manic-depressive insanity; and (*d*) periodic drinking as a psychasthenic impulsion. These distinctions are important, as the different pathological states demand different modes of treatment, corresponding to differences in the mental mechanisms. In dipsomania we are dealing with an interruption in the continuity of consciousness of the same nature as that which occurs in epilepsy, and characterised, as is the dream state of that neurosis, by an amnesia of conservation. In manic-depressive cases, on the other hand, we have to do with periodic variations of mood, while in psychasthenia the impulse acts as though it were an abnormal suggestion thrust into the mind from without. In these latter cases, and in drunkenness generally, when amnesia occurs it is due to the toxic action of alcohol, and is then merely an amnesia of reproduction, in which the lost memories may be revived by various psychological devices. In accordance with its epileptic origin, we find that dipsomania is effectively treated with bromide and salt-free diet, but that it is entirely uninfluenced by psychotherapy. In the other varieties of inebriety, on the contrary, the only treatment of value is some form of suggestion, preferably given in hypnosis. By this method the author claims to have obtained 66 per cent. of recoveries and a further 20 per cent. of improvements in the cases of inebriety which he has treated. A short popular lecture on Alcohol and Work, by Sir Thomas Oliver, is also of interest.

The Universal Medical Record.—With the New Year another addition to the ranks of English medical journalism makes its appearance in the *Universal Medical Record*, edited by Mr. George S. Elliston (London: 36–38, Whitefriars-street. Price 2*s.* 6*d.* each monthly number, or 25*s.* per annum). The first (January) issue contains an instructive paper by Sir Clifford Allbutt on the Importance of Precision in Nomenclature, which it could be wished that every intending contributor to the medical press would read, mark, learn, and inwardly digest. Sir Clifford Allbutt closes his remarks with the assertion that "our present danger is lest the analytic tendency of modern pathology dissolve the outlines of disease drawn by the freehand of our forefathers, who, being farther from the trees, were able better to see the woods." Mr. B. G. A. Moynihan contributes an article on Jejunal Ulcer. A number of presumably editorial articles on various medical and surgical themes are followed by 36 pages of abstracts from current medical literature relating to the various departments of medicine. The abstracts are discriminating.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., Professor ALEX. MACALISTER, Professor ARTHUR THOMSON, Professor ARTHUR KEITH, and Professor ARTHUR ROBINSON. Vol. XLVI. Third Series: Vol. VII., Part II. January Number, 1912. London: Charles Griffin and Co. Annual subscription, 21*s.* post-free.—The current number of this journal contains only four papers. The first of these, by Mr. T. Manners-Smith, occupies considerably more than one-half of the entire subject-matter, and concludes the studies undertaken at Cambridge on the Limb Arteries of the Primates. Twelve coloured plates add to the value of the paper, which, with the parts published in 1910, makes a valuable contribution to our knowledge of the morphology of the vessels of the limbs. Professor J. Symington contributes a paper upon the Topographical Anatomy of the Salivary Glands. This article, which is excellently illustrated, describes the relations of the glands as they are seen in frozen and formalin-hardened sections of the head. The study is a careful one; but although Professor Symington says that "the variations in the shape and relations of the salivary glands are generally slight and unimportant," this is not perhaps the experience of all anatomists and surgeons, and three subjects seem all too few to warrant the findings being necessarily typical. Dr. Douglas E. Derry, in a paper on the Influence of Sex on the Position and Composition of the Human Sacrum, shows how the pelvis in the transition to the upright posture tends to become situated nearer to the hind end of the spinal column. In this migration the female has not gone so far as the male, although the illustrations provided by the author would appear to depict the opposite condition. These facts are undoubted, but it is questionable if they can be called upon to explain more of the variations of the vertebral column than those which fluctuate about the lumbo-sacral region. Dr. F. Wood Jones contributes a description of some cases of Extroversion of the Bladder, and discusses the problems in connexion with this well-recognised condition. These problems are somewhat complex, for they concern the dual origin of the processus vermiformis, as well as the causation of the primary anomaly. The theory put forward by the author hinges on an early distension of the allantois, and many points appear to fit in with this, but it must always be remembered that any "distension" theory, however attractive, cannot be universally acceptable.

Caledonian Medical Journal.—The greater part of the January issue of this journal is a long article by Dr. R. C. Maclagan, of Edinburgh, on various ceremonies and festal observances associated with New Year's Eve in Scotland. As that country may be roughly divided into an English-speaking portion or Lowlands, and a Gaelic-speaking portion or Highlands, it it easy to understand that there are two names for the last day of the year, these being Calluinn in Gaelic and Hogmanay in English. Dr. Maclagan's article is largely philological and contains much information on topics connected with the folk-lore of many nationalities—English, Scotch, Irish, Welsh, Manx, French and Breton, German, ancient Greek, and ancient Roman. Most of it will be of interest to Gaelic scholars. Some critics may consider his philology to be imaginative now and then, as when he suggests that the word Amen after a prayer is derived from Ammon in Egypt, where there was a famous temple of Jupiter, and that the word Jehovah comes from Evoe, the shout of the frenzied congregation at a festival of Bacchus. The paper is very interesting.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Jan. 18th, Sir Francis H. Champneys being in the chair. A letter was considered from the Director of Public Prosecutions with regard to the case of a woman who had tendered a false and fraudulent certificate of birth with the object of being accepted as a candidate at the examination of Dec. 15th, 1911. The Board decided that the Director of Public Prosecutions be thanked for his letter, and that he be informed that the Board acquiesces in the course which he proposes to adopt. A letter was considered from Mr. T. H. Barlow, of 30, Rodney-street, Liverpool, with regard to the difficulty which arose through a mistake having been made at the October examination at Manchester. The secretary presented a draft reply which, after discussion and amendment, was approved by the Board. Sir George Fordham asked leave to propose that application should be made to the Insurance Commissioners that their draft regulations in regard to the maternity benefit should be sent to the Central Midwives Board with a view to the Board's making any observations upon them. The chairman admitted the resolution as a matter of urgency, and it was agreed that the request should be preferred to the Commissioners through the Privy Council.

THE LANCET.

LONDON: SATURDAY, JANUARY 27, 1912.

The National Insurance Act.

IN another column we record briefly the various occurrences of the past week, which go to show that the members of the medical profession are preparing themselves to meet the situation that has been created by the National Insurance Act in a manner creditable to themselves and useful to the community; and it is becoming certain that many divergencies of opinion are more apparent than real.

Our Edinburgh correspondent indicates that the formation of a Central Council in Scotland for the purpose of dealing with the medical questions arising out of the Insurance Act is now within sight. On Saturday last, Jan. 20th, a conference was held under the auspices of the Royal College of Surgeons of Edinburgh, which was attended by members of the governing bodies of the Scottish medical corporations and by representatives of the Universities of Edinburgh, Aberdeen, and Glasgow, a sympathetic message being also received from the University of St. Andrews. At this meeting the many different plans which have been for some weeks discussed crystallised into a simple decision that joint action was desirable, and that a Central Medical Insurance Council for Scotland should be formed, to consist of representatives of the Scottish universities, the medical corporations, the Scottish Committee of the British Medical Association, and delegates from each of some 50 or 60 areas in Scotland. This seems to us to be a most satisfactory procedure, as supplying the profession with exactly the support which it ought to receive in the difficult situation in which all medical men are now placed. The formation of such a Central Council must also impress the public favourably, who, for obvious reasons, are too ready to attribute the discontent of our profession with the Insurance Act to a desire to seize an opportunity for self-aggrandisement at the expense of the community. In particular we welcome this action on the part of the Scottish Universities and corporations, because not only in this way is notice taken of the ominous position of the medical practitioner, but the threat that is uttered by the Act against medical education and the organisation of medical charities is also recognised. The Scottish Central Council has for its object not only to uphold the material rights of those whom it represents, but to consider the effect that the Act may have upon medical education and upon the higher developments of medical science.

We are not without hope that our great medical corporations in England may take a similar step. It is not so easy in England as it is in Scotland to obtain the general coöperation of the universities, which are much more numerous and not so easily comparable with each other. But the majority of our practitioners are Members of the Royal College of Surgeons of England, and very many are also Licentiates of the Royal College of Physicians of London, whether or no they possess also a degree in medicine. We believe that the Royal Colleges might at this juncture serve in a most valuable manner the interests of their Members and Licentiates if they would establish under their ægis, if not actually out of their own governing bodies, a Central Council which would be prepared to take a definite line regardless of the numerous private and personal differences that have so far marked and marred the actions of the medical profession as a whole. Such a council would not be tied down necessarily to the demand for the recognition in the Act of the six cardinal points, and would not be affected by the attitude of one section of the British Medical Association towards another section. In a Central Council, established on large lines, the British Medical Association would receive valuable recognition as the obvious medical organisation to take action in representation of a united profession; while the Central Council would help the Association to decide in what way such action could be most effective. The position of the general hospitals, which play so important a part in medical education, and the position of the students, the great majority of whom may expect to receive diplomas at the hands of the corporations, could be considered by such a Central Council at the same time as they were regarding the professional outlook of those who were already included upon their rolls; and to any sort of pronouncement put forward by such a body the public as well as the medical profession would listen with respect. We believe the guidance of a Central Council promoted by the Royal Colleges would be welcomed in England as a similar body has apparently been welcomed in Scotland; and we believe further that upon the formation of this Central Council a number of persons, now dissenting violently among themselves about details, would be prepared to make a common stand against exploitation of the medical profession, while desirous of associating that profession with any great measure for the advancement of health and the alleviation of misery in this country.

The Medical Profession in India.

WE have received from a valued correspondent in one of the Presidency towns a communication setting forth some aspects of the present dissatisfaction that exists among the native Indian members of the profession, with the object of allaying which we understand the Indian Government is now proposing to make certain important changes. It is perhaps not generally understood at home that the position is really one of considerable complexity, deserving anxious thought. When the Government provided medical treatment for the millions of India it established hospitals and dispensaries, and set on foot an educational system for the training of native medical men. So far as concerns the native troops of the Indian Army, these are medically cared for by European, Eurasian, or native medical officers, under whom is a large staff of "hospital assistants" (or, as

they have been recently styled, "sub-assistant surgeons"), who have been professionally trained for their position during three years by the State, but are not technically "qualified" practitioners. The British troops are attended by European medical officers, under whom serve the Indian Subordinate Medical Department, composed of "assistant surgeons"; these are of European or Eurasian parentage, have also been professionally educated (during four years) by the State, and frequently possess great experience and professional skill, but they are not, as a rule, technically "qualified" practitioners. The hospital assistant class are also largely employed throughout the country in subordinate charge of civil hospitals, and some military assistant surgeons also discharge civil duties, though available for military duty if required.

The ordinary native medical practitioner, not in Government service, who has obtained a licence in medicine and surgery after five years' study and who practises independently as a native doctor, generally speaking amongst the poorer inhabitants, is not, as a rule, so efficient as either of the other two classes, though his curriculum of study has been longer; for he practises by himself, whereas the other two classes do their work to a great extent under the supervision of European medical men, and are quick to assimilate the skill and experience of these latter. The two former classes have been educated at Government expense, and they remain in Government service because, in nearly every case, they have no legal qualification to practise independently; occasionally they do take out full qualifications, sometimes even going to Europe for the purpose; but these are quite exceptional cases. It must be allowed that the condition of things is not ideal; many of these subordinate officers are really extremely capable men, but they are not technically "qualified"; on the other hand, there are a great number of "native doctors" all over the country, possessed of a technical qualification, but really very imperfectly educated, and owing to the circumstances of their position not really capable of developing into a professional body of high standing. It is not perhaps generally realised that India is almost overrun with native doctors of various degrees of professional ability; the great complaint is that the cities are overstocked with them, all trying to scrape together a living, but apparently forced to follow dubious courses of professional conduct, such as advertising or the sale of nostrums, in order to make both ends meet. For it should be understood that these practitioners are not generally of independent means; the Indian gentleman of substance does not often put his son into the medical profession, he sends him into law; not only does the law offer greater pecuniary rewards (for going to law is one of the chief pleasures of a large part of the population), but its opportunities are greater, and the prestige it carries is considerably superior.

Now, it is only with a high standard of professional attainment that a good type of student can be attracted to any profession; in the present case a higher standard would mean fewer doctors, but these few would obtain a living wage, and some of them would attain eminence, either professionally, or scientifically, or financially, and so induce others to emulate them. According to present conditions it has to be acknowledged that India does not turn out a high class of practitioner. There has recently been an outcry that the native doctor does not get a fair chance of improving his professional knowledge and position, since all the appointments and professorships at the medical colleges are in the hands of the official Indian Medical Service. It must be admitted that this is the case, and if the service considers appointments of this nature to be its reward for hard work and expatriation, surely there is a great deal to be said for the view. A great service cannot be recruited unless there are some tangible and dignified returns. However that may be, it is quite certain that the "independent" body of native practitioners must study harder and must have a higher standard of general culture before they can be considered capable of occupying professorial appointments. It would, we believe, be generally admitted by those conversant with the facts that even in the large cities, where native doctors of a good type are to be found, their status of professional attainments is not sufficient to qualify them satisfactorily to hold a professorship. The advance of education has been extraordinarily rapid in the large centres of India during recent years; it is not in the least surprising that there should be discontent at the deficiency of pecuniary rewards and prospects among those who have qualified themselves by examination for the exercise of a profession. The situation is not an easy one to deal with; but (1) there must be a gradual and deliberate evolution and development before the office of *teaching* can be safely entrusted to the hands of a class that have only been themselves *learners* for little more than a single generation; and (2) there must be more evidence than has at present appeared of a pursuit of knowledge for its own sake, of a desire for research, before the higher offices of teaching can be committed to Indian medical graduates. There have been a few brilliant exceptions; but the intellectual characteristic of the class that enter our profession in India has been aptitude for the acquisition of knowledge, rather than capacity for original research. It might also be said that they have been especially liable to suffer from what BACON called the first distemper of learning, when men study words rather than things.

Annotations.

"Ne quid nimis."

THE PREVALENCE OF THE NEUROPATHIC TAINT.

IT is a commonplace of psychiatry that a kinship of origin connects several of the different clinical forms of mental disease not only with one another but also with the numerous eccentricities of thought and conduct that are met with in individuals of that large and ill-defined class formerly described as "degenerates." These latter minor abnormalities may therefore be regarded as indicating a morbid tendency in the stock, and since this tendency may be expressed in graver forms of decadence in later generations, the prevalence of such neuropathic conditions is a matter which must nearly concern the vitality of the race. On this account there is an obvious practical interest in endeavouring to ascertain to what extent these conditions are really present in the general population. As statistics bearing directly on this point do not, however, exist, we are obliged to have recourse

to indirect methods of inquiry, and of these the most promising would appear to be the method which proposes to use the known amount of certifiable insanity as an index of the total amount of degeneracy of which it is the most extreme expression. Data which can be used in this way may be collected, in what should soon be sufficient quantity, from the series of detailed pedigrees which are being worked out with so much care and industry in recent investigations dealing with the hereditary factor in insanity. In one of the latest of these investigations, reported by Dr. A. J. Rosanoff and Miss Florence Orb in the *American Journal of Insanity* for October, 1911, special reference is made to this point. The writers, after an apparently adequate scrutiny of the history of each of the neuropathic individuals, 437 in all, included in the pedigrees which they have studied, arrive at the conclusion that only 115, or 26·3 per cent., presented at any time in their lives indications for commitment to asylums for the insane. If, therefore, this percentage is to be regarded as fairly representative of the proportion of certifiable cases in an average series of individuals showing neuropathic symptoms it would be necessary to multiply the number of certified lunatics in the community by about four to find a true estimate of the incidence of the neuropathic taint in the general population. It is interesting to note that this ratio of the certifiably insane in the degenerate families studied by Dr. Rosanoff and Miss Orb corresponds very closely with Dr. Mott's estimate of the proportion of offspring of insane parentage who themselves become insane—viz., 1 in 4 or 5.[1] Dr. Rosanoff and Miss Orb, who approach the question from the Mendelian point of view, suggest that it is necessary to take account further of those individuals who, though themselves normal, are carrying the neuropathic taint as a latent character, and they bring forward some rather speculative arguments tending to show that a relatively large proportion of the general population may be in this unsound state. However that may be, the facts reported in their interesting paper are a useful reminder that our available restrictive measures, which deal only with the patently insane, and but intermittently and ineffectively even with them, touch no more than a fraction of the tainted members of the community, and for that reason can be of little influence in checking national degeneracy. The remarks of Dr. T. Claye Shaw (in a lecture on the Mental Processes in Sanity and Insanity at p. 211) bear on this matter.

KING EDWARD'S HOSPITAL FUND AND THE EVELINA HOSPITAL.

THE chairman of the Evelina Hospital for Sick Children, Mr. D. Malcolm Scott, has published an explanation of the omission of that charity from the list of awards granted to hospitals by the King Edward VII. Hospital Fund Committee. From this statement of the case for the Evelina Hospital it appears that in 1909 the King's Fund suggested that the hospital should appoint an "inquiry officer," and in December of that year a grant of £150 was made on condition that such an officer was appointed. As a matter of fact, the experiment cost the hospital over £200 a year, so that the management were actually some £50 a year out of pocket. The governing body of the hospital then referred the matter to a subcommittee, and the result was that the plan was adopted of establishing a Samaritan Fund in order that the almoner, or "inquiry officer," should have means at her disposal to assist necessitous patients. The next year, 1910, the hospital received a legacy of £3620, left unconditionally; and it was decided, under legal advice, to allocate the sum to the Samaritan Fund. The King's Fund objected to this, and informed the Evelina authorities that the money must be transferred to the general fund; failing compliance, the annual grant was imperilled. The hospital committee refused to alter its decision, and the result is that the Evelina Hospital receives no grant this year from the King's Fund. On the merits of the whole case it is not easy to decide, since Mr. Scott's version is necessarily an *ex parte* statement. But if it is assumed that the facts are as set forth, and that no considerations other than those alleged have determined the attitude of the King's Fund, it would certainly seem that a very rigid discipline is being enforced. The King's Fund insisted on an almoner at the Evelina Hospital, and paid the greater part of the cost. A Samaritan Fund is a recognised and approved adjunct of an almoner's work, and exists at many other hospitals without interference from the King's Fund. Therefore, it may be inferred that to the Samaritan Fund itself the King's Fund has no objection. Since the Samaritan Fund has to be financed somehow, the difference between endowing it with the interest of a legacy and contributing the same sum annually from the income of the hospital is, to the ordinary mind, one of accounts. In either case the principal sum is retained as an asset of the hospital, and in either case the interest on it is applied to one of the legitimate purposes of the charity. We do not understand the principle which has guided the King's Fund, unless, indeed, the £3620 was to be spent instead of being invested as an endowment for the Samaritan Fund. The exact destination of a legacy seems to be the proper province of the managers of a hospital, and the function of the King's Fund should be rather to see that it is not squandered or applied to purposes other than those for which the hospital exists. Too much interference with the internal economy of individual hospitals is to be deprecated.

THE MINE-DUST PROBLEM IN SOUTH AFRICA.

THE difficulties of dealing with dust in mines are acknowledged to be extremely great, and the subject has received the closest attention from every point of view. As is well known, in South Africa pulmonary affections in miners are of frequent occurrence, and "miners' phthisis" produced by the dust occasions a high mortality. In THE LANCET of Dec. 2nd, 1911, p. 1588, we published a letter from Mr. J. L. Aymard, of Johannesburg, charging the mine-owners and Government with neglect by not generally enforcing measures which had been found to be successful in the Nanse mines. In our issue of Jan. 13th, p. 121, will be found a letter from Dr. Charles Porter (medical officer of health of Johannesburg) and others, giving the history of the Mining Regulations Commission, which, though well known in Johannesburg, is naturally little known elsewhere. This letter throws a more favourable light on the proceedings of the Commission, and it is gratifying to learn that practically all of its recommendations, including those regarding dust prevention, mine ventilation and air standards, scavenging, water-supply, and so on, were promulgated almost verbatim as regulations with the force of law. These regulations are also printed after the letter. We have received another communication from Mr. Aymard in the form of a paper which was submitted at the monthly meeting of the Chemical, Metallurgical, and Mining Society of South Africa on Jan. 21st of last year. In this paper many points are discussed in relation to miners' phthisis and its prevention. He quotes Dr. J. H. L. Cumpston, an Australian Government medical official, who in a recent report holds the view that the very finest dust merely circulates in the

[1] Inborn Factors of Nervous and Mental Disease, Presidential Address to the Neurological Section of the Royal Society of Medicine.

blood without doing any material harm, and he contends that it is a coarser dust which, by its constant passage through the air channels, causes the fibrous growth. Mr. Aymard discusses at length the various procedures which he considers necessary to help to solve the dust problem. Since this paper was read, as will be seen by the regulations above mentioned, a great deal has been accomplished to remedy the defects which have hitherto existed. This will do much to decrease the anxiety which has been felt, and doubtless by enforcing the regulations which have been formulated the incidence of miners' phthisis will be materially lessened.

RUPTURE OF THE BRACHIAL ARTERY DURING FOOTBALL.

IN the *Australian Medical Journal* of Nov. 25th, 1911, Dr. W. Moore has reported a rare accident during football—rupture of the brachial artery. A man, aged 21 years, was playing on August 26th. The ball was kicked down the centre of the ground. He ran from one side, whilst an opposing player ran from the other side. They both jumped for the ball and touched one another in the air and fell to the ground. The patient rose to his feet immediately, found his right arm painful at the elbow, and noticed a large swelling at the inner side of the front of the elbow. He walked off the ground holding the right wrist with his left hand. When examined in the dressing-room the right hand and forearm were found pale and cold, and there was considerable swelling about the right elbow and a rounded lump about the size of a hen's egg at the front and inner aspect. The lump was very hard and did not fluctuate or pulsate, and the skin over it was abraded. At the wrist no pulse could be felt. Within five minutes of the accident the hand and arm had become absolutely pale and corpse-like. They were quite cold and devoid of sensibility. No injury to the bones or elbow-joint could be made out. The patient's colour was good, but the pulse at the left wrist was feeble. The arm was wrapped in cotton-wool and bandaged. It seemed that the brachial artery had been torn across just above its bifurcation. The inner and middle coats might have curled up, allowing very little blood to pass. Dr. Moore feared that it would be necessary to incise freely and clear out the clot to relieve tension, and then to secure the vessel. But a little over an hour later the hand was slightly warmer, the extreme pallor had disappeared, and some sensibility had returned. The hard lump at the elbow had disappeared, and there was a general soft swelling at the elbow and upper part of the forearm and lower part of the arm. No pulse could be felt at the wrist. The limb was wrapped more thoroughly in cotton-wool, carefully bandaged, kept almost fully extended, and raised on a pillow. About four hours later the arm was again examined and sensibility was found quite distinct. The swelling had extended almost into the axilla and to the distal third of the forearm. There was no pulse at the wrist. A skiagram taken next morning showed that the bones and joint were intact. Sensibility in the limb was good and it was warm. The finger-nails were fairly red and the colour returned to them quickly after pressure was removed. There was still no pulse at the wrist, and the arm and forearm were much swollen. The arm was bandaged, slightly flexed at the elbow, and the patient was allowed to get up. On August 29th there was further improvement and he was allowed to go out. Two days later he was much better, but in the morning he noticed that the right hand was colder than the left. He was very tender about the elbow, where there was a slight localised swelling at the front and inner side. There was no sign of pulsation at the site of the injury. The arm was still greatly swollen from the axilla almost to the wrist, but most at the elbow. There was brownish, yellow, and blue discolouration from the axilla to the wrist. The arm was still wrapped in cotton-wool and bandaged, and was carried in a sling. On Sept. 6th the swelling was much less and was most marked at the back of the elbow. There was distinct hardness at the front and inner side, and over this was a small scab. The patient could extend the arm fully. Pulsation could be felt in the brachial artery below the middle of the arm but not traced to the elbow. The bandage was left off and gentle massage was ordered. On the 13th the swelling and discolouration were much less and a feeble radial pulse could be felt. On Oct. 2nd movements of the arm were practically normal. The right arm was smaller than the left from wasting of the muscles. There was still a little hardness on the front and inner side of the elbow-joint, which was distinctly tender. The pulse could easily be felt at the wrist, but pulsation in the brachial artery could not be traced to the elbow.

CRUMB AND CRUST.

LAY discussion not infrequently turns upon the relative merits of the crust and crumb of bread, but it has come to our attention that the matter is often referred to the family medical adviser, generally in the form of a question as to which of the two is more digestible. Analysis shows very little difference in regard to the constituents of each, but the crust, of course, contains much less moisture, and so is richer in solid constituents. The crumb contains on an average 43 per cent. of moisture, while the crust contains only 20 per cent. One important dietetic difference between crust and crumb is the fact that the former contains an increased amount of soluble carbohydrates owing to the action of intense heat which the crust receives compared with the crumb during baking. Moreover, the crust has a more pronounced "bready" flavour than the crumb, a flavour which is attractive and which stimulates the flow of digestive juices. That the digestion of crust in the mouth is much more likely to be complete than is the case with the crumb everyone has generally found out for himself, as the plasticity of the crumb, and especially that of new bread, prevents to some extent the salivary attack. If new bread were as thoroughly masticated as dry stale bread is bound to be, there would be no reason why it should be less digestible, but it seldom receives the necessary treatment in the mouth.

SPONTANEOUS HÆMORRHAGE INTO THE KIDNEY.

HÆMORRHAGE into the substance of the kidney, or into the peri-renal tissues, is a fairly common result of injury to the abdomen; but apart from this it is a rare event. The principal causes are aneurysm of the renal artery or one of its branches, of which there are 26 recorded instances, injury causing the arterial lesion in a majority; new growths of the kidney, intense congestion in the course of a nephritis, and arterial disease without aneurysm. There is also an interesting and mysterious group of cases to which the term "renal apoplexy" has been applied. The case recorded by Dr. R. S. Fowler in the *Annals of Surgery* for December, 1911, is of this latter type. A woman, 52 years of age, was attacked ten days before admission with a dull pain in the back, which soon became more severe and was associated with considerable hæmaturia. Micturition, though not abnormally frequent, was accompanied by sharp pain in the left renal area, and the left lumbar region was tender. There was a chill with fever, and the patient vomited several times. No cause could be assigned for these symptoms. Examination disclosed a fixed, tender swelling in the neighbourhood of the left

kidney as large as a cocoanut. There was no evidence of a stone, and the urine contained nothing abnormal apart from a microscopic quantity of blood and a few hyaline casts. The case was regarded as one of hydronephrosis. At the operation, however, a large amount of blood was found in the left peri-renal region, and the capsule of the kidney was torn. It was thought wise to perform nephrectomy, after which the patient recovered completely. A careful examination of the kidney failed to disclose any reason for the hæmorrhage, which had apparently originated in the cortex near the lower pole, spreading subsequently to the pelvis, and also to the peri-renal tissues through the rent in the capsule. Fowler gives an interesting summary of the recorded cases, and says that there are apparently two distinct pathological conditions, one in which the hæmorrhage begins in the renal substance and spreads into the surrounding tissues later, as in the case recorded by him, and the other arising in the fatty capsule of the kidney. This latter type is comparable to the hæmorrhage which may occur after slight exertion in obese persons into fatty tissues in other situations. Whatever the origin, the blood may burst through into the peritoneal cavity. In the eight cases recorded there was no special incidence as regards either age or sex. The onset was sudden in every instance, with pain referred to that side of the abdomen which corresponded to the affected kidney and usually with some shock. Three times the urine was normal. In all cases a tumour could be felt; in three instances there was local discolouration of the skin. Diagnosis is obviously difficult. Fowler recommends operation in every case: if the hæmorrhage arises from the peri-renal tissues these should be excised, while if the source of the blood lies within the kidney itself nephrectomy is necessary. The infiltrated tissues should be freely removed in order to avert the septic infection which is liable to follow.

THE VISCERAL LESIONS OF EPIDEMIC POLIOMYELITIS.

IN THE LANCET of Jan. 20th, p. 181, we commented upon certain aspects of the epidemiology of epidemic poliomyelitis. We have since received a reprint of a note published in the *Journal of the American Medical Association* of Jan. 13th by Professor Simon Flexner, Dr. Francis W. Peabody, and Dr. George Draper, of New York, upon the visceral lesions of human cases of this disease. They point out that in 1888 Rissler described swelling of the agminated and solitary follicles of the intestine and enlargement of the mesenteric glands and spleen in two children, and swelling of the spleen without changes in the mesenteric glands in an adult, the cases having been observed clinically by Medin. Similar changes, together with enlargement of the thymus, were described in 1910 by Strauss in four children dying during the acute stage of the disease. Harbitz and Scheel and Wickman have also referred to the hypertrophy of the lymphoid tissue of the intestine and the spleen in children. Professor Flexner and his collaborators have examined the organs from 11 children dying from the disease, their ages ranging from 3½ months to 9½ years. Ten of the children died between the third and the eleventh day of the disease. The remaining one, having survived the acute stage of the disease, died two months later from laryngeal diphtheria. They found in all of these cases some hypertrophy of the lymphoid tissues, which was widespread if not universal, and included the tonsils, small intestine, thymus, and the superficial and deep lymphatic glands. The spleen was enlarged, the Malpighian bodies were prominent, and the pulp was increased. Microscopically changes were also found in the parenchymatous organs. The changes in the lymphoid structures consist of hyperplasia of the cells of the lymph nodes and of the lymph sinuses of the lymphatic glands. The changes in the parenchymatous organs were chiefly observed in the lungs and in the liver. The lungs in several instances showed within the capillary and other small vessels a considerable number of myeloid cells of the megakaryocytic type. The changes in the liver were conspicuous and apparently constant, and consisted of hyaline, focal necrosis of liver cells, followed by regeneration and invasion by lymphoid cells and polynuclear leucocytes. The number of these areas of necrosis was remarkably large, and the rapidity with which regeneration was attempted was a striking feature. Professor Flexner, Dr. Peabody, and Dr. Draper, therefore, conclude that epidemic poliomyelitis is one of the diseases in which the organs generally suffer injury, the main stress of which falls upon the nervous system, then upon the lymphatic structures, and lastly upon the parenchymatous organs. Whether these lesions, exclusive of those of the nervous system, are to be attributed to parasitic action, or to the action of toxic elements of parasitic origin, they state can only be a matter of conjecture at present. Their observations constitute a further addition to our knowledge of this important disease, and are worthy of note as enlarging our conception of its nature and effects.

ANTIVACCINATION TACTICS IN INDIA.

A SHORT while ago we received from an Indian correspondent a communication calling our attention to a pamphlet that was being circulated in India, entitled "Small-pox and Vaccination in British India." The pamphlet can now be obtained in this country we understand. The futility of wasting space in a medical journal to go on killing the dead has long been obvious. It is hardly likely that 1 per cent. of the medical profession need any further demonstration of the utility of vaccination than their own studies and experience have brought them. The general public, on the other hand, which does need the instruction, would be more appropriately and successfully reached by competent writers through the lay press. We have looked through the pamphlet, which is a reprint of letters and other contributions addressed by antivaccinationists to some 150 Indian papers. There are also two voluminous criticisms of a book (bearing the same title as this pamphlet) by Major S. P. James, I.M.S., statistical officer to the Government of India. The pamphlet consists of the usual compound of illogical deduction, inaccurate statement, and wild assertion—such, for instance, as that cancer, consumption, paralysis, epilepsy and St. Vitus's dance, and defective teeth in the younger generation have vaccination as the main cause of their prevalence. We are further told that "zymotic diseases are caused by bad food, famine, overcrowding, bad drainage, neglect, dirty houses, and impure soil, lack of pure water, and filthy surroundings"—which, of course, is about as correct as it would be to say that the wheat crop is caused by fertile soil. Again, we are told that "the experience of the British Isles, however, has proved that the only thing that matters where small-pox is concerned is the presence or absence of dirt, neglect, overcrowding, bad air, or bad food." Notwithstanding this, an argument against vaccination is based on the fact that "the statistics of soldiers attacked by small-pox in India show a heavier death-rate per million men than that per million living in the British Isles, in spite of the fact that the soldiers are thoroughly vaccinated and revaccinated, are in the prime of life, and are properly looked after"; and that "the countries mentioned contain a large proportion of very young, very old, delicate, neglected, unvaccinated, unwashed,

ill-fed, and crowded inhabitants, while the army of India consists of picked men in the prime of life who are properly cared for in every way." Any deduction that can be drawn from these data tells just as much against "the only thing that matters where small-pox is concerned," namely sanitation, as against vaccination. The pamphlet, in its notice of Major James's book, adopts the view that the admitted decline in small-pox is chiefly due to the suppression of the practice of inoculation, and cites in support thereof the testimony of Major James that the provinces in which small-pox has declined least—viz., Bengal, Assam, and Lower Burma—are the provinces which Major James himself names as being hot-beds of inoculation. When, however, Major James points out that the diminution of small-pox also "has been very great in provinces where inoculation was never practised widely, if at all," the rebuttal is spoken of as "feeble." It is not Major James's argument that is "feeble." Again, when in support of his contention that vaccination has mitigated the severity of small-pox in India Major James quotes figures showing that out of 1118 vaccinated people attacked with small-pox there were only 97 deaths (a mortality of 8·6 per cent.), while out of 1177 unvaccinated people attacked there were 610 deaths (a mortality of 51·8 per cent.), and further supports it by showing that the case-mortality of 1691 European troops and 3420 native troops, all well vaccinated, is only 10·1 and 7·7 respectively, the only comment made is: "We need not take up space in exposing the farcical character of the Major's unvaccinated fatality rate." There is, in fact, absolutely nothing in the pamphlet calling for fresh consideration, for its argument is in no sense novel, but of the kind to which we have been treated *ad nauseam*. On the other hand, long experience shows that the conversion of the professional agitator is practically never accomplished, though, as in the case of a former health officer of Cleveland, U.S.A., an academic antivaccinationist who has been temporarily led astray by specious arguments has occasionally found them dissolve into nothing before the logic of inexorable fact encountered at first hand. The pamphlet, of course, contains the usual railing at the mercenary character of the medical support of vaccination. "We know that gold appealed powerfully to Jenner; to say, therefore, that vaccinators in this country are actuated by the desire for lucre is simply to assert that they preserve intact the traditions of their profession" (p. 8), and more to the same effect. It will hardly be suggested, however, that the members of the medical profession at large are influenced by a desire for lucre in getting vaccinated and revaccinated themselves, and still less in insisting on vaccination and revaccination for their wives, children, and all whom they hold dear.

TUMOURS OF THE PINEAL BODY.

AN interesting paper upon the symptomatology of tumours of the pineal body, based upon a study of a case of teratoma of that organ and upon a review of all the recorded cases of pineal tumour, is published in the *Archives of Internal Medicine* of Dec. 15th, 1911, by Dr. Pearce Bailey and Dr. Smith Ely Jelliffe, of New York. They give a brief account of the origin, histological structure, and anatomical relations of the pineal body. After the seventh year of life the normal pineal body undergoes a process of involution, the ganglion cells disappear, the glia cells persist, and the connective tissue is increased. The glandular cells become more vacuolated and their nuclei more prominent and pigmented. The view that it is in part a rudiment of a third eye, like that of the Hatteria punctata, is doubted by Cajal, who asserts that it is one of the many blood glands of the body. The symptoms produced by tumour of this body may be those indicative of brain tumour with certain focal signs, and, in addition, certain distinct and noteworthy disturbances in nutrition, so that in some cases the diagnosis may become reasonably certain. The neurological symptoms are at first those due to increased intracranial pressure resulting from the hydrocephalus which often develops with great rapidity, owing to pressure on the veins of Galen and obstruction to the aqueduct of Sylvius. There are also some reasons for believing that growths in the region of the pineal body may stimulate the production of cerebro-spinal fluid. Headache is usually the first symptom. Papillary œdema soon develops, and half of the patients have become blind. Abnormal drowsiness has been observed in many cases, even in the early stages. Certain motor phenomena, such as increased muscular tonus, weakness without paralysis of the extremities, and increased tendon reflexes may be due to the hydrocephalus alone, but when the tumour reaches a certain size it usually gives rise to special symptoms from pressure upon such structures as the corpora quadrigemina, the floor of the aqueduct, and the superior peduncles of the cerebellum. Pressure on the corpora quadrigemina gives rise to ocular and pupillary signs similar to those of tumours of these structures. Isolated eye palsies are common, and occasionally develop very early. Nystagmoid movements or nystagmus often occur. The pupils are usually widely dilated, frequently unequal, and are sluggish both to light and on accommodation. Facial palsies, slight and usually unilateral, and certain auditory symptoms, such as buzzing in the ear or advancing deafness, have also been observed. Pressure on the cerebellar peduncles may lead to the suspicion of cerebellar tumour. Giddiness and dizziness have been constant; staggering gait has been an early sign in nearly half the recorded cases. Polydipsia and polyuria have been recorded, and are probably due, according to Dr. Bailey and Dr. Jelliffe, to remote pressure on the fourth ventricle. The recognition of the metabolic symptoms produced by tumours of the pineal body is due to Marburg. These appear to be adiposis, early sexual maturity, and cachexia. The adiposis seems to be independent of the nature of the tumour. It is known that disease of the hypophysis may lead to adiposis, and as yet it cannot be definitely decided whether the adiposis occurring in pineal tumours is due to disturbance in the function of the pineal body itself or to interference with the hypophysis through the hydrocephalus of the third ventricle. The sexual changes have been enlargement of the penis, increase in the genital hair, early masturbation, and sometimes changes in the voice. The explanation of these changes is also difficult, more particularly as to their relation to the pineal body or the hypophysis. The third metabolic symptom is cachexia, and as yet it is not determined whether this has any special relation to the pineal body, the tumour, or the hydrocephalus. The case observed by Dr. Bailey and Dr. Jelliffe was a boy, aged 12, admitted for failing memory and difficulty in walking. He had grown very rapidly and was markedly fat. His voice was high-pitched, and he was sleepy and apathetic. He showed a papilloedema of 2 diopters in each eye. Movements of the eyes upwards were completely lost, the superior oblique was affected, and movements outwards were diminished. There was an irregular nystagmus at times. The pupils were equal, irregular in outline, and reacted sluggishly. Hearing was poor and vision was also affected. There was a coarse tremor of both hands together with a good deal of ataxia. The knee and ankle reflexes were exaggerated; ankle clonus and the Babinski and Oppenheim reflexes were present on both sides. While in the hospital, the left side of the face became weaker than the right, and the boy's gait became very ataxic. At the necropsy, made three hours

after death, there was a large amount of cloudy cerebro-spinal fluid, and there was marked distension of the third ventricle. On section, a large rounded encapsulated tumour about 1½ inches in diameter was found replacing the pineal body. It was soft and consisted of sebaceous matter, hair, and pieces of cartilage. Brief histories are also given of 59 cases from the literature, several of which have been recorded in THE LANCET, one of them as long ago as 1837.[1] Dr. Bailey and Dr. Jelliffe have performed a useful service in the careful recording of their own case and in supplying such a complete study of the other cases in the literature.

PRAISE AND BLAME.

THE suggestion that when it is found that the seller has sold goods which on analysis under the Sale of Food and Drugs Acts prove to be genuine he should receive a certificate to that effect deserves careful consideration. Of course, when it happens that the goods are not genuine considerable publicity is commonly given to that fact. We think, therefore, that the request for well-earned praise is logical, provided that no abuse of the issuing of such a certificate is capable of being put into practice. It may be urged that the certificate would be used for purposes of advertisement, but it seems to us that there can be no objection even if that were done. The grocer who exhibits a certificate of genuineness of one or other of his goods would be encouraged, we imagine, to keep up the whole of his commodities to a high standard lest the merited certificate should be stultified by disclosure of subsequent offence. If he decides not to advertise the certificate its purport will at least afford him the satisfaction, which he does not get directly or definitely now, that his goods have passed the requirements of the food laws. The system would have the further advantage that if in the analyst's opinion the sample was perilously near condemnation the shopkeeper might be warned.

THE FEBRILE FORM OF CANCER OF THE RECTUM.

CANCER of the rectum is often overlooked. The patient may preserve all the appearances of health or show only progressive anæmia without any local symptoms.[2] At a meeting of the Société Médicale des Hôpitaux of Paris on Dec. 1st last M. J. Thiroloix and M. Mora reported a rare case in which the local and general symptoms of cancer of the rectum were absent, and the disease manifested itself as a chronic cryptogenic infection with daily rises of temperature such as may be produced by a chronic inflammation of one of the natural cavities (biliary or urinary passages, bronchi, nasal sinuses, or appendix). Still more curious, the general symptoms—fever, anæmia, and wasting—were not uniformly progressive, but regressed and disappeared, and the patient appeared to regain perfect health. A robust man, an engineer, aged 41 years, came under observation. He was athletic, sober, and intelligent, and a careful observer of the least derangement of his health. None of his relatives had suffered from cancer, and his mother was living. He had never had syphilis or any other serious disease. Early in February, 1911, he had febrile attacks every afternoon which consisted of three stages—shivering, hot, and sweating. The rectal temperature rose to from 102·8° to 104° F., and the attack lasted from three to four hours. On the following morning he was fairly well and could continue to direct works of which he had charge. His general health was little affected; he became a little pale, lost some flesh, and was fatigued more readily than previously. Appetite, digestion, and sleep were unimpaired. The perfect daily periodicity of the attacks suggested malaria, but parasites could not be found in the blood, which always showed the same conditions—hypoglobulia and hyperleucocytosis with polynucleosis. Cultures of the blood were negative. All the organs were normal on examination. He never complained of any pain or trouble in defæcation. For four months (February to May) the intermittent quotidian fever remained of the same type, but showed great variations. During complete rest the evening temperature was only 98·6° to 100·4°, while after fatigue it reached 102·2° to 104°. Quinine in large doses had an undoubted action on the fever, which it reduced. In April the anæmia was very marked. The spleen was large and easily felt, and there was a double continuous souffle in the veins of the neck. Thus all the facts seemed in favour of the diagnosis of malaria. In April the medullin of Merck and the cytuline of Couturieux (the juice of yeast and nucleinate of soda) were given in addition to quinine, and his general condition greatly improved. In June the temperature fell, the anæmia disappeared, and strength was regained, and he was sent to the country to complete his convalescence. In September he returned a different man. He had gained from 8 to 10 kilogrammes in weight; he had a good colour and a normal spleen and temperature. His life was accepted by an assurance company which had declined it in January. On Sept. 24th he complained of great pain in the anus which was bearable at ordinary times but terrible on defæcation. It was thought that he must be suffering from anal fissure. On introducing the finger into the rectum on Oct. 4th the pain was so great that he nearly fainted. Though the examination was brief, hard growths could be felt surrounding the upper orifice of the anal canal. Under chloroform a more complete examination was made on the following day, and cancer involving the lower third of the rectum and invading the anus was found. The ano-rectal region was covered with growths, hard below and soft above, which bled on the slightest touch. Excision was performed and death from pulmonary embolism occurred four days after the operation. Microscopic examination showed that the growth was a columnar epithelioma of the rectum which involved the sphincter ani. The moral of this case is that a rectal examination should be made in all cases of febrile anæmia of which the cause cannot be found.

THROMBOSIS OF THE ABDOMINAL AORTA AND OBLITERATIVE ARTERITIS IN THE SAME CASE.

THROMBOSIS of the abdominal aorta is very rare. In the *Yale Medical Journal* for October, 1911, Dr. George Blumer has reported a case which derives additional interest from the fact that obliterative arteritis also occurred. A Russian Jew pedlar, aged 48 years, was admitted into hospital on Jan. 5th, 1909, complaining of pain in the left foot. There was no history of syphilis. Three days before admission, after exposure to cold, he took a Russian bath. Severe cramp in the left leg and foot followed. The foot was so tender that even the pressure of the bed-clothes caused extreme pain and sleep was prevented. The pain was paroxysmal. The patient was well nourished. At the apices of the lungs there was diminished resonance and a few moist râles were heard. The heart was normal and the pulse regular, but there was slight diffuse thickening of the radial artery. In the left femoral artery pulsation was diminished, and the left second, third, and fourth toes were blue and cold and their sensibility was diminished. The blueness extended to about the middle of the foot and the remaining part was red and shiny. The junction of the cyanotic and red areas was very sensitive. Pulsation of the arteries of the foot was feeble. Dry gangrene of the parts supplied by the dorsalis pedis and the branches of the internal plantar artery developed, and on Feb. 12th the leg was amputated at the

[1] S. Stanley: Dropsy of the Pineal Gland, THE LANCET, 1837, p. 935.
[2] THE LANCET, Dec. 30th, 1911, p 1821.

junction of the middle and upper thirds. Healing was perfect and he was discharged on March 4th. On June 18th, 1911, he was readmitted, complaining of great pain in the thighs and gluteal regions. Two hours previously he had fallen to the ground with agonising pain in the back. On admission the pain was so severe that he could not lie recumbent or sit up; he therefore assumed a semi-recumbent posture. The pain was stabbing in character. The right leg and foot felt numb and cold. When seen by Dr. Blumer next morning he was perspiring freely, looked very anxious, and evidently suffered great pain. The abdomen was not distended, but there was a distinct spasm of the abdominal muscles in the lower zones. Pulsation could not be felt in the abdominal aorta. The stump of the left leg was blue and cold to a point 16 centimetres above the knee, and there was doubtful pulsation in the femoral artery. The right leg was cold and cyanotic as far as the middle of the thigh, and pulsation could not be felt in the femoral artery or its branches. Sensation to touch and pain was impaired in both stump and leg. On the right side the knee-jerk was abolished. There was no definite gangrene. On the following day the eyes were sunken and the expression anxious with rather pinched features. The pulse was feebler and more rapid. The cyanosis had extended as high as the buttocks. There was no gangrene of the foot or stump, but on the anterior surface of the scrotum there were two or three superficial areas of dry necrosis. The urine, which was secreted freely, contained a trace of albumin and some hyaline casts. The patient failed rapidly and died on the following morning. Thrombosis of the abdominal aorta between the origin of the renal arteries and the bifurcation was diagnosed. Only a partial necropsy was permitted. There was chronic pulmonary tuberculosis of the fibroid type at both apices. The heart was flabby and its muscle pale and cloudy-looking. On the coronary arteries were a few patches of early arteriosclerosis. The aorta showed only slight sclerosis. The liver and kidneys showed cloudy swelling. In the abdominal aorta just above the bifurcation of the iliacs was a fresh, white, slightly adherent, occluding thrombus, capped above by a red thrombus which reached almost to the origin of the renal arteries. The symptoms and signs were characteristic of thrombosis of the abdominal aorta. The extreme rapidity of onset might have led to a suspicion of embolism rather than thrombosis, but this rapidity has been noticed in previous cases. There was no evidence in the heart or upper part of the aorta of a pre-existing thrombus which might have been detached. On the other hand, the appearances of the lesions were those of thrombosis. There is one point in the case not mentioned in Dr. Blumer's commentary—the patient's race. Dr. F. Parkes Weber has pointed out the comparative frequency of obliterative arteritis among male Jews of the East End of London, some of whom smoke a large number of cigarettes. He suggests that unwholesome food and racial factors play a part. J. Israel has also drawn attention to the occurrence of idiopathic gangrene in Russian Jews.

THE DEATH OF SIR HENRY BUTLIN.

WE have to record with much regret the death of Sir Henry Trentham Butlin, Bart., which took place on Wednesday, Jan. 24th, at his residence in Harley-street. It is only 11 weeks ago that we announced his resignation of the Presidency of the Royal College of Surgeons of England owing to ill health, and expressed on behalf of the profession the hope that with that release from public duties his strength would be restored. Sir Henry Butlin was equally distinguished as a surgeon and as a leader of the profession, and his personality and his many gifts can ill be spared at this critical time. He held many high positions and adorned them all.

THE King has given to Dr. Charles Todd, of the Public Health Department at Cairo, His Majesty's Royal licence and authority to accept and wear the decoration of the Third Class of the Imperial Ottoman Order of the Medjidieh, which has been conferred upon him by His Highness the Khedive of Egypt in recognition of valuable services rendered.

WILL SICKNESS BE INCREASED UNDER THE INSURANCE ACT?

BY FRANK MILTON, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE PROFESSOR OF CLINICAL SURGERY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE, CAIRO.

I HAVE no intention of touching upon the question of what would be adequate remuneration for work under the Act; but, since the scale of remuneration must ultimately be based upon the amount of work to be done, it is of interest to try to get some idea as to the probable increase in the amount of sickness likely to be developed by the Act.

In 1910 I was asked by the Association of Carnarvonshire Slate Quarry Owners to go into the question of the surgical results of the Workmen's Compensation Act, and to give evidence on their behalf before the Royal Commission on Metalliferous Mines and Quarries. With this object in view I was supplied with the returns of accidents in six of the largest quarries under the association for the years 1900 to 1909 inclusive. These returns included all accidents known to the management of the quarries concerned, and probably included all accidents which were sufficiently severe to cause a man to absent himself from work.

The number of men employed in these quarries varied from year to year, but for the whole period the average number was 1750 actual employees.

The points to be kept in mind are, that under the original Act compensation was only paid to an injured person after the expiration of 15 days' disablement, and the compensation began on the fifteenth day, the first two weeks of actual disablement not being compensated; but that under the present Act, which came into force on July 1st, 1907, compensation begins at the end of the first week, and if the disablement lasts more than 14 days the claim to compensation is dated back to the day of the accident. It thus happens that if a man receives an injury which disables him for 14 days he gets compensation for seven days only; but if the disablement lasts for 15 days he gets compensated for the whole period.

Before coming to the actual figures it may be premised that slate-quarrying is a fairly hazardous employment, the fatalities being 0·14 per cent. of the men employed, and the severe accidents—that is, accidents involving the fracture of a bone, dislocations, injury to the eye involving impairment of vision, and multiple injuries—being 0·34 per cent. Owing, however, to the nature of the material handled the number of cuts, especially cuts of the fingers and hand, is large, these being due to the excessively sharp edge of the newly split slate. Suppuration does not, as a rule, follow these cuts, and as they are simple incised wounds their healing is rapid and their treatment simple.

In Table I. is given the number of men employed year by year, the total number of accidents of all kinds, and the percentage of accidents to the number of men employed, the latter being visualised in Chart 1. It will be noticed that at the beginning of the period (in 1900) the percentage of accidents was small, being only 1·56 per cent., and rising in 1901 to 2·13 per cent. It is possible that during these early years accidents were not recorded with the care that it was found necessary to give to them later on, and that the cause of the men being absent from work was not inquired into with the same strictness that now holds. This might have, in part, accounted for the small number registered, but that the smallness of the number was not entirely due to this is shown by the fall which occurred between 1903 and 1906, when the percentage fell below that for 1901.

With the coming into force of the present Act in 1907 a

TABLE III. (*Chart 3*).—*Percentage of Men Employed Disabled for Two Weeks and less than Three.*

Year.	Cases.	Per 100 men.
1900	3	0·150
1901	2	0·101
1902	11	0·557
1903	7	0·374
1904	10	0·526
1905	2	0·126
1906	3	0·186
1907	9	0·584
1908	28	1·928
1909	28	1·912
Total.	103	0·588

large rise took place, and the percentage jumped from 2·0 to 4·6; and in 1908, the first complete year under the new Act, the percentage, as compared with 1906, increased no less than threefold, and remained nearly as high in 1909.

I was directly interested in one of the quarries concerned, and I made careful inquiries as to the other quarries to see if there had been any alteration in the methods or conditions of working which might have in any way accounted for, or helped towards, this increase in the number of accidents; but whilst the increase had occurred in each one of the quarries, in no case had any alteration been made in the system of working which could have had any tendency to increase the number of accidents.

Table II. shows the total accidents, the severe and the minor being differentiated. Under the heading "Severe" are included all fatal accidents, all accidents involving fractures and dislocations, all injuries to the eye causing permanent impairment of vision, and all multiple injuries.

By this table it will be seen that whilst the severe accidents have not undergone any increase in late years, the whole of the rise in the percentage has been due to the increased number of minor accidents.

The increase in the more trivial accidents noted in Tables I. and II. would certainly suggest that the benefits received under the Compensation Act of 1907 might have had something to do with the alteration in their number. Remembering that the full benefit under the Act is not secured until the disability has lasted a full fortnight, it becomes of interest to see what has been the effect on the number of cases under treatment during this critical period. Table III. accordingly has been constructed to show the percentage of men employed who were under treatment for two weeks and less than three. From this it will be seen that, as compared with the years 1905 and 1906, the years immediately preceding the coming into force of the new Act, the percentage of employees remaining under treatment for 15 days and less than 21 has increased more than tenfold.

In face of these figures it is difficult to avoid coming to the conclusion that the benefits to be obtained under the Workmen's Compensation Act have had a distinct tendency towards increasing the number of cases of accident applying for treatment.

I wish here to say a word on the question of malingering. The impression likely to be created by the foregoing is that some, at any rate, of this increase is due to malingering on the part of the men, but I am convinced that this impression would be a wrong one. I have had occasion to become closely acquainted with a large number of the men supplying the basis of these figures, and without having been medically responsible for the treatment of their injuries I have had a very close knowledge of what they have been suffering from, and I do not know of a single case in which true malingering could have been alleged. The class of men concerned in these records are, for the most part, a highly intelligent, hard-working, and steady lot, in no way inferior to the skilled workmen found in similar occupations all over the country; and although I have only had access to the returns relating to this one occupation I have no reason to doubt that if the returns of any other hazardous trade in the United Kingdom were analysed the result would be very similar.

This being so, the question which has to be faced by us is this: If, in the case of accidents where the lesion is plain and the question of disability is comparatively simple, the number of cases occurring has increased fourfold under the stimulus of the Workmen's Compensation Act, what will be the rate of increase in the number of cases of disease where the disability may depend largely upon the subjective symptoms as experienced by the patient, whose sufferings may possibly be accentuated by the consciousness that, though he be kept from work, there will be a certain amount of money coming in?

And when to this certain increase is added the increase due to patients—instead of, as now, having to go to see their doctor during his hours—being entitled to call their own chosen man in at any time that may suit their own convenience by day or night, and all this tempered by the very human desire to secure full value for money paid, the tale of attendances is likely to mount to heights far beyond any possible present calculation. And yet it is upon an estimate of what the increase in the number of cases is likely to be that the question of "adequate remuneration" must be settled.

It is obvious that *if* 6*s.* a year a head is a fair price for the work under present conditions, should the cases increase fourfold or fivefold, as would seem possible from the figures given above, then the remuneration must also increase in proportion, and the price to be paid must be reckoned in pounds rather than in shillings.

Ramsgate.

INTERNATIONAL HYGIENE EXHIBITION, DRESDEN, 1911.

REPORT OF THE BRITISH COMMITTEE.

THE following highly satisfactory report has just been issued by the British Committee of the International Hygiene Exhibition, Dresden.

The report, which is signed by Sir Thomas Barlow (chairman), Lord Ilkeston (treasurer), and Mr. H. W. Armit (secretary), states that: "The great exhibition at Dresden has served two large purposes. It has been the means of placing on record the scientific achievements in the realms of hygiene from the earliest times up to the present, thus assisting the expert in his endeavour to progress. It has also served a vast humanitarian purpose in instructing millions of lay visitors with regard to health, the dangers associated with the various modes of life, and the best means of avoiding these dangers." We can support this statement, which has already been developed in articles in THE LANCET.[1]

The report then continues:—

"*Its International Character.*

The exhibition was primarily a German undertaking, but the fact that all the civilised nations were invited to coöperate in carrying out the humanitarian object rendered it truly international. Among the States officially represented were Austria, Brazil, China, France, Hungary, Italy, Japan and Formosa, Russia, Spain, and Switzerland. It became a necessity, in order that Great Britain should not earn the reputation of an unfriendly nation, that our country should also join hands with Germany in attempting to improve the health conditions of the whole world.

The Government Commissions.

Each of the States represented had a special pavilion. The respective Governments appointed a Commission and voted a sum of money for the equipment of the section and for the proper management of the same. The Commissions were placed under the care of a Chief Commissioner, save in the case of Japan, which had six Commissioners, acting conjointly. In each section a staff of assistants and clerks were engaged to carry out the business of the section. Sums varying up to £35,000 were voted for the purpose by the various Governments.

The British Section.

Owing to the refusal of the British Government to undertake to organise the British Section this duty devolved on the committee appointed *ad hoc*. The difficulties with which the committee had to contend were partly due to the smallness of the financial support, partly to the lateness of beginning which was occasioned by the difficulty in obtaining funds, and partly by the exclusion of support of Governmental departments. An exception to the last-named was found in the case of the Board of Education, which lent a small but valuable exhibit dealing with the hygiene of schools.

In spite of the necessity of economising by acquiring a small pavilion the British Section was by no means the smallest in regard to the number and variety of exhibits. The scheme followed was to illustrate a large number of British methods of dealing with the various hygienic problems. The exhibits were, for the most part, not prepared with a view to elaborate elegant display, but in practically every case scientific excellence was the primary consideration. A catalogue of the section will be sent on application, enclosing 2*d.* for postage, to any subscriber or member of the committee.

The committee was represented by the secretary, who conducted the work without the assistance of a staff, thereby

[1] THE LANCET, vol. ii., 1911, pp. 547, 712, 1162.

effecting a considerable economy. During the period of the exhibition the committee were continually in receipt of congratulations on the excellence of their work, and the presence of the British section was obviously appreciated in no small degree, as may be gathered from the fact that it was visited by large crowds of visitors, among whom were the leaders of the various hygienic professions of practically every country. Numbers of experts paid repeated visits to the section.

The Financial Statement.

The accounts of the committee have been audited by Mr. F. W. Osborne, certified accountant. His statement is appended below. As will be seen, the sum of £4784 14*s.* 6*d.* was subscribed by the public for the purpose of equipping the section. Not allowing for certain receipts in respect of the sale of furniture, &c., the expenditure of the committee was £4214 13*s.* 2*d*, leaving a balance of £707 3*s.* 8*d.* Of this balance £396 8*s.* have been returned to the guarantors, who, in response to a request, converted their guarantees into subscriptions, and who have now received the sums thus given, back in full. A further balance remains of £310 15*s.* 8*d.*, of which a certain small sum will be required for the purpose of winding up the business of the committee.

The committee suggests that the ultimate balance, which is estimated at £275, should be devoted to a cause which is most closely connected with the object for which the funds were originally given. It appears to this committee that such an object is the Parkes Museum of the Royal Sanitary Institute. It is therefore proposed by the committee that the sum available be given to the Royal Sanitary Institute on the condition that it be used for the improvement of the Parkes Museum. This will be carried into effect if the subscribers consent.

Thanks of the Committee to the Subscribers.

In conclusion, the British Committee of the International Hygiene Exhibition desire to express their best thanks to the generous subscribers, who have enabled them to carry out their task to the evident satisfaction of their German hosts and of the visitors to the exhibition."

Summary of Financial Statement.

We congratulate the committee on their public-spirited action and practical success. They maintained the position of this country as leaders in hygiene with a very insufficient backing and an unfortunate lack of official support. It is unnecessary to publish the vouched account of receipts and expenditure alluded to as "appended below," as a brief statement will cover all the ground. The committee received all told just short of £5000. Some £660 were returned to the guarantors or remain as balance. The expense of maintaining the pavilion, including cost of building electric and water installation, electric fittings, furniture, decorations, lighting, cleaning, attendants' wages, &c., was £1305 10*s.* 3*d.* The management expenses, including salaries, clerical and general expenses, printing, stationery, postages, telegrams, travelling expenses, cost of appeal, and charges incurred in London office amounted to £2151 16*s.* 8*d.* The exhibits' account, including show cases, stands, insurance, transport and packing, was £757 6*s.* 3*d.* The small balance is accounted for by winding up expenses.

THE WEST AFRICAN MEDICAL STAFF: AN INTERESTING DINNER.

THE winter dinner of the West African Medical Staff took place on Friday last, Jan. 19th, at the Trocadéro Restaurant, London, when there was a large gathering of the past and present members of the staff.

Dr. W. T. Prout, C.M.G., of the Liverpool School of Tropical Medicine, late principal medical officer of the West African Medical Service, presided, and the guest of the evening was the Right Hon. L. Harcourt, Secretary of State for the Colonies. Other guests were: Sir Ronald Ross, K.C.B.; Mr. A. Fiddian, Mr. W. A. Robinson, and Mr. D. L. H. Baynes, of the Colonial Office; Mr. Kenneth Millican, of the staff of THE LANCET; Major C. H. Armitage, C.M.G., D.S.O., Chief Commissioner, Northern Territories, Gold Coast; Mr. R. H. Maude, Solicitor-General of the Gold Coast; Dr. A. E. Cooper; and Staff-Surgeon H. Hunt, R.N. The senior members of the staff present included Dr. R. M. Forde, principal medical officer, Sierra Leone; Dr. P. J. Garland, C.M.G., late deputy principal medical officer, Gold Coast; Dr. E. H. Tweedy, deputy principal medical officer, Gold Coast; Dr. F. Manning, deputy principal medical officer, Northern Nigeria; Captain W. H. G. H. Best, provincial medical officer; and Dr. St. George Gray and Dr. W. F. Macfarlane, senior medical officers.

After the toast of the King had been duly honoured, the chairman called upon Dr. Langley Hunt, who was leaving the staff, to propose the toast of prosperity to that staff.

Dr. LANGLEY HUNT said that it would be a difficult matter to over-estimate the importance of the West African Medical Staff as a factor in the civilisation of the colonies concerned, and it was only those who had come into close contact with the natives who could realise the value of gaining their confidence. He looked upon the staff as a most important asset in the development of West Africa, and he was certain their influence would increase, and that they would continue to maintain the high reputation which they had earned.

Dr. PROUT, in proposing the health of their distinguished guest, the Secretary of State for the Colonies, and their other guests, said that he felt it was almost an impertinence to attempt anything in the way of a speech in the presence of one who was accustomed to the flights of oratory which he was credibly assured was the daily nutriment of the House of Commons. They welcomed the Secretary of State not only as the head of the Colonial Office, but because they recognised in him the actual head of the West African Medical Staff—the final arbiter to whom all questions connected with their profession on the coast must finally be referred, and by whom they must be decided. It was a source of gratification to them that he had found time, amidst the many claims of a busy official life, to show his appreciation of their work by honouring them with his presence there. It would be an act of presumption on his part to attempt to refer to the multifarious duties and responsibilities of a Secretary of State for the Colonies, but there was one direction which closely affected them—namely, the attitude which a Colonial Secretary might take up towards the great question of medical research and tropical hygiene; and it was a matter for congratulation that they had had at the Colonial Office a succession of statesmen who had fully realised the vital importance of putting these matters in the foreground. He had himself been associated for over 25 years with the tropics, and had seen a great change come over the attitude of the public and of the official mind. Formerly tropical diseases were regarded with a species of fatalism, which was possibly largely due to the lack of knowledge of their causes. But now, owing to the advances of tropical research, it was realised that diseases in the tropics were as preventable as those in temperate climates, while it was essential for the economic development and future civilisation of the colonies that they should first be made healthy. And among those who had had the privilege of administering the colonies no one had shown a greater interest in all questions of medical research, had given greater encouragement to tropical sanitation, and had shown a more sympathetic appreciation of the work of the medical profession than the present Secretary of State for the Colonies. He (the speaker) had had, as a member of the Advisory Committee to the Colonial Office, many opportunities of becoming personally acquainted with the keen interest which Mr. Harcourt took in these matters, and would instance as an example the Nyasaland Commission on Sleeping Sickness, which was largely due to that gentleman's personal influence. It was often said that the Colonial Office did not do enough and did not give enough money, but they must remember that behind them was a stern and inexorable Treasury, from which it was much less easy to extract money than, say, to extract a recalcitrant molar from the jaw of a negro; and while they, like Oliver Twist, asked for more they were grateful for what Mr. Harcourt had succeeded in doing. If he might for a moment be permitted to dream, he foresaw in the Advisory Committee to the Colonial Office the nucleus of a vast Imperial health organisation, with its headquarters in the seat of the empire, but with ramifications extending all over the globe, reinforced by men of eminence in science in this country, and mainly staffed by those who had had a personal knowledge and experience of the problems to be dealt with in the colonies. There would be departments to deal with different diseases, to collect

statistics, to collate information, and to stimulate research, and the health of that great Empire of which we are so proud would be promoted. Dr. Prout concluded by alluding to the great work done by Sir Ronald Ross and by welcoming the permanent officials of the Colonial Office, because unofficial meetings promoted good feeling and a better understanding between those who worked abroad and those whose work lay at home.

In responding to the toast of his health, the SECRETARY of STATE for the COLONIES said: "I esteem it an especial honour to be the guest of the West African Medical Staff, and I am deeply grateful for the terms in which your chairman has proposed this toast. Never since the days of Daniel has there been witnessed such an act of signal courage as the presence at this moment of a Cabinet Minister at a dinner of doctors. Perhaps I ought to attribute the hospitable immunity I have so far enjoyed to the fact that in West Africa—a land of ordinance rather than of legislation—there is for the present at least no Insurance Bill. I forbear from sketching for you the touching picture of a head of a house sticking stamps upon a missing card for an equally missing Jimmy Johnstone, or a doctor under contract speeding down the unfinished Bauchi line in a special to diagnose a tin-miner for ankylostomiasis. But in all seriousness, and home politics apart, I wish to assure you of the gratification it is to me to have this opportunity of expressing to you, and through you to all your colleagues, my deep gratitude for, and high appreciation of, the splendid services you are rendering in your exile to the cause of humanity and Empire. A Colonial Secretary, whatever his tastes, however deep his ignorance, must, by his daily experience and anxieties, become a 'médecin malgré lui.' I do not, however, admit myself to be wholly an ignoramus. It has been one of my relaxations in life—I do not say it as commendation to you—to have been in medicine a judicious mixture of the quack, the empiric, and the amateur. You will, no doubt, after such a description wonder why I have not long ago appeared before the coroner. The reason is that in the last resort my valour has been so subject to my discretion that in anything more serious than a common cold I have generally sought the advice and paid the fee of those who are qualified to give the one and receive the other. Perhaps I may be permitted the harmless gratification of saying in my own justification that I was one of the first, is not *the* first, now thirty years ago, to experiment with the leaves of Erythroxylon coca (then a little known plant obtained for me from South America by the Editor of THE LANCET), and with the tincture, I myself made the cocaine, to procure, I believe for the first time, the complete and rather alarming anæsthesia of the throat and eye. If I could have retained an exclusive knowledge of its effect on the vocal cords, how much trouble and suffering I might have saved by its secret administration in my present profession to opponents and colleagues.

But, gentlemen, I am not going to inflict anything on you in the way of a speech; this is only the exordium to an imminent peroration. I said just now that in the Colonial Office one must be, or ought to be, Molière's 'involuntary physician.' I say this because perhaps the saddest incidents of an anxious day are the telegrams which pour in on me from all quarters of the globe of yellow fever here, plague there, blackwater fever somewhere else, malaria almost everywhere, sleeping sickness in ill-defined and, I fear, extending regions. There is pathos, as one of your colleagues has written in 'Lyra Nigeria,' in the—

> Thought of the workers of yesterday,
> The men on whose bones we build.

And there is a sardonic truth in his picture of life on the coast as—

> The woof of farce, together bound
> By warp of grimmest Tragedy.

I wish that by my words to you to-night I could bring home to the rest of you who are fighting the great fight in the swamps, the jungle, and the desert, that we, who live at home in so-called ease, chained to an administrative desk, are not unconscious and not unmindful of the hopes, the fears, the struggles, and the triumphs of the pioneers of tropical medicine. As the area of research broadens while it concentrates, your opportunities for distinction and achievement extend with the painstaking record of receptive and perceptive minds. If Condy's fluid could make Colon into a sanatorium, there should be no limit to your aspirations. I am comforted and consoled by the thought that there is in your pursuits, what is essential to a Briton, an element of sport. Foxes may be scarce and hounds deficient, but you can always pursue the stegomyia of yellow fever to its earth in a jam-pot, or have a drive of mosquitoes to be decimated with a syringe. I am not sure that your colleagues in Central Africa may not have to become big game hunters if Glossina morsitans is going to affect the vices of its degenerate brother palpalis.

If I talk lightly after dinner of these incidents, do not imagine that I take anything but a serious view of your difficulties, your duties, and your prospects. If it were not for my official position I should tell you that as a private individual I consider you to be miserably underpaid, but departmentally I avoid any further reference to the stipend you are *willing* to accept. This at least I will say, that the insufficiency of the material rewards you reap seems to have no discouraging influence on the efficiency of your service. You have some experimental advantages and opportunities of practical research which are denied to your stay-at-home colleagues. You are occupying one of the actual fields on which the battles of new methods are being fought and their results tested. In the domain of pure medicine I suppose that it would be true to say that, apart from synthetic drugs, no true prophylactic has been discovered since Jesuit's bark developed into quinine. But the work on other lines of Pasteur, Koch, Almroth Wright, Sir Ronald Ross, and Rubert Boyce—though not commanding by any means universal assent—has opened new avenues of fruitful inquiry and fertile hopes. It may not be what Sir Benjamin Brodie once called 'ideal chemistry,' but it is full of possibilities which may stir the imagination of the most phlegmatic. It is true that much caution is required lest the latest hypotheses should be too readily accepted as postulates, but nearly all great discoveries have advanced through the experimental adoption of unproved—sometimes unprovable—assumptions. You are, by the locality of your practice, specially interested in the study, the treatment, and the cure of yellow fever. I should share the usual and proper fate of amateurs if I ventured upon the dangerous discussion of the differentiation of yellow fever from bilious remittent as distinguished by black vomit, or if I trenched upon the speculation as to semi-immunity derived from adolescent and unrecognised attacks. I only mention these doubts and discussions because I am sure we all feel that all avenues of possible progress should not be closed by prejudice or prejudgment.

Research is not an end—it is only a means. But it is true that it is also one of the pleasures of life to him who knows how to pursue it. The pursuit of truth—even when unsuccessful—has given happiness to generations of great scientists; its attainment is the golden crown reserved for the very few. If a time came when all was known, when investigation and experiment were at an end, half the pleasure and profit of life would have died with the knowledge. We may remain happy, then, in the anticipation of the possession of knowledge yet unwon. The questioning of Nature, the causes of disease, the problems of life and death, will last as long as the generations of mankind. I apologise to you for the excursions of an ignoramus. They have been made not as the speculations of a thinker, but to try to show you that in all that concerns your great profession, in the services you render, in the results you attain, you have a true friend and well-wisher in Downing-street."

Sir RONALD ROSS also briefly responded, and said that progress in tropical sanitation was now really going ahead. It generally took about ten years before any new discovery in medicine was accepted, and it was just over ten years since the transmission of malaria was definitely explained. He thought that though the Americans had done much in the way of the application of tropical sanitation, England, which was first in the field, still showed the way in tropical research and medicine. He was sure that a new era was dawning for West Africa, and he was confident the West African Medical Staff would do all in their power to forward it.

Dr. FORDE then proposed the health of the chairman, who suitably responded, after which an adjournment was made to the ante-room, where the Secretary of State took the opportunity of making the personal acquaintance of members of the staff.

THE INAUGURAL DINNER OF THE MEDICAL OFFICERS' JOINT COMMITTEE.

AT a meeting of the Association of Medical Officers of Health which was held in the summer of 1910 the possibility of forming a federation of all the various societies of part-time medical officers was discussed, and last year a joint permanent committee, consisting of representatives of Poor-law medical officers, public vaccinators, postal medical officers, police surgeons, certifying factory surgeons, and Metropolitan Water Board surgeons, was formed, Dr. Rashell T. Davison, Dr. Crookshank, and Mr. D. A. Belilios being appointed to represent the Association of Medical Officers of Health. The committee so formed may be taken to represent the interests of between 7000 and 8000 medical men, and on Jan. 19th its first annual dinner was held at the Holborn Restaurant. A well-managed dinner and a wisely arranged programme of instrumental and vocal music lightened the proceedings without diverting the attention of those present from their main object—viz., the discussion of the disabilities which threaten the medical profession at the present moment and which call for a wise and united action among part-time medical officers. Mr. H. Bott presided over a representative company.

After the loyal toasts, which were proposed by Mr. BOTT, had been honoured,

Dr. MAJOR GREENWOOD proposed the toast of the evening, "The Joint Committee of the Medical Officers' Associations." He said there never was a time when union among the members of the profession included in this most important toast was more necessary. The part-time medical officer and the general practitioner formed a very large proportion of the profession, and their power would be great if they would stand together. Any jealousy existing between the constituent associations, and between them and the general practitioners who did not hold appointments, must be resolutely suppressed, and the importance of combination kept constantly before them all. Like a destroying angel recent legislation had fallen upon them, and indirectly, if not directly, most of the associations represented at that gathering would be affected. The joint committee could do nothing to avert the evil unless it was backed up by the rank and file of the profession. He most sincerely hoped that the committee would receive whole-hearted support.

Mr. BOTT, in his reply, said he was confident that the joint committee, which had been inaugurated by the Association of Medical Officers of Health, would be a very powerful engine in assisting not only part-time medical officers, but also the general practitioners throughout the country. He then briefly sketched the history of the attempt to dispense with the services of part-time medical officers, who, he believed, served the interests of the public health better than the whole-time men; and pointed out that the part-time men knew the district in which they were engaged, they were more in touch with the community, and their comparative financial independence gave them exceptional opportunities for securing acceptance of their views. If the part-time officer was abolished, sooner or later the medical officer of health would have thrust upon him all the medical appointments of his district without being adequately remunerated. One of the natural expectations of the general practitioner was to secure a public appointment in his own district; but unless the part-time officer and the general practitioner banded themselves together in a community of interest they would find themselves in a very serious position. On all sides an attempt was being made to take away from them their just rights, and he hoped that the opposition to the Insurance Act would be the means of inducing the whole of the profession affected by it to join the Medical Officers' Association. Seven or eight thousand practitioners would be a force that could move any Government. If they were true to themselves they would be adequately paid for their work.

Mr. G. ELLISTON, in proposing "The Constituent Associations," a toast which he coupled with the names of Dr. Davison and the Presidents of the various associations, reiterated the need for a strong combination, remarking that the number of associations represented was an eloquent testimony of interest and future action.

Dr. RASHELL DAVISON, after referring to the inauguration of the public health service, said that if the Public Health Department was satisfactory to the nation it might be claimed that the department was built up by the part-time officers. Mr. Fremantle, the county medical officer of Hertfordshire, and other medical officers of health had supported the Association of Medical Officers of Health in every possible way because they knew the good work that had been done by the part-time medical officer. He hoped that the Association of Medical Officers of Health and the Joint Committee would take important places among the societies of the profession.

Mr. G. H. W. PARKINSON urged that the part-time medical officers should recognise that their interests were common to each other. If any of the part-time departments were successfully attacked the others would also suffer. The time had come when it was absolutely necessary for the general practitioner to unite in the protection of themselves. Branches of the Association of Medical Officers of Health should be formed all over the country, spreading the good work they were doing, strengthening themselves, and helping the general practitioner.

Dr. A. WITHERS GREEN emphasised the views of the previous speakers.

Dr. A. E. COPE exhorted the profession not to allow sanitary matters to be involved in politics. It was very important that one kind of appointment should not be allowed to merge into another kind, for that meant the cutting down of adequate remuneration.

Dr. JOHN MATHIESON also replied.

Dr. C. OWEN FOWLER proposed the toast of "The Guests," coupled with the names of Sir John Collie, Mr. A. G. R. Foulerton, and Mr. Michael H. Taylor.

Sir R. J. COLLIE, in replying, said that out of 70 medical members of the Metropolitan Water Board no less than 68 had joined the Association of Medical Officers of Health.

Mr. FOULERTON said the interests of the public and the profession were identical. If the profession was degraded the public would suffer from a bad service. A State service should be well paid, but a combined general and clinical service with a minimum salary would be a very bad thing for the country. Such a State service would put the standard of professional education back. The part-time officer was an absolutely necessary servant of the State. The medical profession had more influence if it chose to use it than any other profession in the country. With regard to the Insurance Act, the alternative, if the profession gave way, was the appointment of a badly paid public service. If the bulk of the profession stood together this could be defeated. The Joint Committee represented the men who would stand or fall by what happened in the course of the next 12 months, and he hoped the profession would not allow themselves to be misled by specious promises.

Mr. TAYLOR also replied.

Dr. CROOKSHANK, in proposing a vote of thanks to the chairman, explained the idea of the Association of Medical Officers of Health in bringing together the Joint Committee at a dinner, and expressed the general approval of the appointment of Mr. Bott as its chairman.

Mr. BOTT briefly replied and the meeting terminated.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Nottingham.—The population of this county at the date of last year's Census was 344,135; its rate of increase during 1901–10 has been considerably greater than that during 1891–1901. The birth-rate remains high, 29·9 per 1000 in the urban and 25·2 in the rural districts. As in some other counties, this is mainly to be attributed to the presence of a large coal-mining population. The town of Mansfield, with 35,738 inhabitants, showed a birth-rate for 1910 of 33·1, and the adjoining district of Mansfield-Woodhouse a rate as high as 39·8. In reporting on administration of the Midwives Act, Dr. Henry Handford refers to the fact that the new rules of the Central Midwives Board practically take away such powers of suspension as the local supervising authority formerly possessed. He considers that the finding of a *primâ facie* case of negligence or misconduct with subsequent investigation and decision by the Central Midwives Board requires at least three or four months and sometimes longer, and that exceptionally much harm may be done in

the meantime. During 1910 the notices of sending for medical help were 365, out of 4120 maternity cases attended by midwives, or 8·8 per cent. In regard to isolation hospitals the arrangements in this county have for some time been at a standstill, and are likely to remain so in the absence of action by the county authorities to unite districts for hospital purposes. There has been a small but quite definite increase during 1910 both in the number of deaths from pulmonary tuberculosis and in the deaths from other forms of tuberculous disease; the county rates stand at 0·77 and 0·48 respectively. Dealing with tuberculous milk and the inquiries made in Nottinghamshire under the milk clauses of the London Acts Dr. Handford points out that so long as very little is being done in most parts of the county to prevent milk containing tubercle bacilli from being sold, no reasonable complaint can be made of London taking steps to protect itself, but under the procedure adopted there is nothing to prevent the diseased milk which has been rejected by London from being consumed locally or sent to Nottingham or other large towns. He strongly advocates improvement in ventilation of cowsheds, and keeping cows merely in open sheds, and protests against medical officers of health being ridiculed for advising in agricultural matters of this kind. The natural laws which govern human health and disease apply in many respects to the higher mammals also, and are not merely "an appanage of agriculture" where the cow is concerned. Mechanical milkers, which are now in use in several places, prevent dust and dirt falling into the milk pail, but introduce a new danger from the difficulty of cleaning the long india-rubber tubes which form a necessary part of the apparatus. It is the old trouble of the long tube of the babies' feeding-bottle in a new form. The tubes should be sterilised by steam each time they are used. In this, as in several other counties, the direction of sampling under the Food and Drugs Acts and administration in regard to adulteration of food appears to be undertaken by the police, without any reference to the sanitary officers of the county council.

County of Gloucester.— Dr. J. Middleton Martin reviews the attempts which have been made to remove the infectivity of scarlet fever by inunction and swabbing on the lines recommended by Dr. R. Milne, the experimental trial of which in Gloucestershire was advocated by the late Dr. F. T. Bond and adopted in the Cirencester isolation hospital and elsewhere. He concludes that there is great variation in the infectivity of cases, and that our present knowledge is insufficient to decide definitely (apart from patients with discharges) which are actively infective and which are not; apparent success in any line of action would follow if we dealt with the second class of case alone, while failure would similarly be the result of any lack of proper precautions of the first class. In his view it would be most unfortunate if, as appears to have been done in one district at least, those responsible for the protection of the public health advised delay in making proper provision on the very slender evidence thus far adduced in the matter. Dr. Martin insists that the increasing knowledge of the manner in which disease may be carried by house flies makes it now specially necessary for small local authorities to put their arrangements for public scavenging on a better footing or to undertake scavenging which hitherto has been left to householders. It would appear from annual reports that systematic scavenging is only undertaken in ten urban districts and in very few villages in the county.

County of Cambridge.—Dr. F. Robinson expresses much satisfaction at the passing of the Cambridge Water Company's Act, the provisions of which will result in the abandonment of the suspicious sources of supply from the wells in the chalk to which public attention was drawn a few years ago, and the addition of water from a new and satisfactory source. Apart from the areas which this company supplies, there has been considerable activity in dealing with the problems of water-supply in this county, which are particularly difficult, as no large upland surface supplies are available and the risks of pollution of underground water are by no means negligible. A detailed list of the chalk water-supplies in the Newmarket and Linton rural district appears in the report, but would have been of greater value if the opportunities of pollution, as ascertained by local investigation and by the use of fluorescin had been indicated in each instance. During 1910 arrangements were made by the county authorities for bacteriological examinations for the detection of diphtheria in elementary schools. The county council adopts the useful practice of making grants in aid of isolation hospitals in the county, after inspection and recommendation by its medical officer. Dr. Robinson urges the advantage of a central small-pox hospital to serve the whole of Cambridgeshire.

VITAL STATISTICS.

VITAL STATISTICS FOR 1911.

THE following statement shows the birth- and death-rates and the rates of infantile mortality in England and Wales and in certain parts of the country during the year 1911, the figures being provisional:—

—	Annual rates per 1000 living.			Deaths under one year to 1000 births.
	Births.	Deaths.		
		Crude.	Corrected.*	
England and Wales	24·4	14·6	14·6	130
77 great towns including London	25·6	15·5	16·4	140
136 smaller towns	23·4	13·8	14·4	133
England and Wales less the 213 towns	23·4	13·9	13·1	118
London	25·0	15·0	15·8	128

* The corrected death-rates are the rates which would have been recorded had the age and sex constitution of the populations of the several areas been identical with that of England and Wales as enumerated in 1901.

The aggregate death-rates from the principal epidemic diseases have not been calculated in the General Register Office, and cannot therefore be included in the table. On the other hand, figures relating to London have been added to the table.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 7638 births and 4979 deaths were registered during the week ending Jan. 20th. The annual rate of mortality in these towns, which had been 15·3 and 15·4 per 1000 in the two preceding weeks, declined to 14·8 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual rate of mortality in these large towns averaged 15·2 per 1000, while in London during the same period the average annual death-rate did not exceed 14·7 per 1000. The annual death-rates last week in the several towns ranged from 5·2 in Gloucester, 8·7 in Acton, 9·1 in Ipswich, 9·4 in Leyton, and 9·8 in Lincoln, to 21·3 in Walsall, 22·7 in Merthyr Tydfil, 25·0 in West Bromwich, 26·3 in Dewsbury, and 30·4 in Dudley.

The 4979 deaths from all causes in the 94 towns were 193 fewer than the number in the previous week, and included 297 which were referred to the principal epidemic diseases, against 313 and 323 in the two preceding weeks. These 297 deaths from the principal epidemic diseases included 81 from whooping-cough, 64 from measles, 60 from diphtheria, 55 from infantile diarrhœal diseases, 19 from scarlet fever, 17 from enteric fever, and 1 from small-pox. The mean annual death-rate from these diseases last week was equal to 0·9 per 1000, against 1·0 in the preceding week. The deaths attributed to whooping-cough, which had been 78 and 88 in the two preceding weeks, fell to 81 last week, and caused the highest annual death-rates of 1·3 in Gateshead, 1·6 in St. Helens, 1·9 in Gillingham and in Merthyr Tydfil, 2·0 in Barnsley, 2·3 in Edmonton, and 2·8 in Walsall. The deaths referred to measles, which had been 83 and 69 in the two previous weeks, further declined to 64 last week; the highest death-rates from this disease were 1·1 in Manchester, 1·3 in Norwich, and 1·4 in Warrington and in Burnley. The fatal cases of diphtheria, which had been 49 and 69 in the two previous weeks, fell last week to 60, and included 15 in London and its suburban districts, 7 in Liverpool, 6 in Leeds, 5 in Manchester, and 3 each in Gillingham, Birmingham, and Leicester. The deaths attributed to infantile diarrhœal diseases numbered

55, against 57 and 58 in the two preceding weeks; 19 deaths were registered in London and its suburban districts, 7 in Liverpool, and 6 in Birmingham. The 19 deaths referred to scarlet fever were equal to the number in the previous week, and included 2 in Birmingham and 2 in Liverpool. The 17 fatal cases of enteric fever, which were 5 fewer than the average in the two preceding weeks, included 4 in London and 2 each in Stoke-on-Trent, Stockport, and Rotherham. The death from small-pox was registered in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily decreased from 2213 to 1762 in the nine preceding weeks, had further declined to 1654 on Saturday last; 162 new cases of this disease were admitted to these institutions during the week, against 162, 193, and 165 in the three preceding weeks. These hospitals also contained on Saturday last 1201 cases of diphtheria, 306 of whooping-cough, 117 of measles, and 47 of enteric fever, but not one of small-pox. The 1217 deaths from all causes recorded in London were 42 less than the number in the previous week, and were equal to an annual death-rate of 14·0 per 1000. The deaths referred to diseases of the respiratory system, which had been 381 and 290 in the two preceding weeks, rose to 303 in the week under notice, but were 64 less than the number registered in the corresponding week of last year.

Of the 4979 deaths in the 94 large towns last week 190 were referred to different forms of violence, and 433 were the subject of coroners' inquests. The causes of 51, or 1·0 per cent., of the deaths registered in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and its 14 suburban districts, Sheffield, Leeds, Bristol, Bradford, Newcastle-on-Tyne, Portsmouth, Salford, and in 48 other smaller towns. The 51 uncertified causes of death last week included 10 in Birmingham, 4 in Stoke-on-Trent, 4 in Liverpool, and 3 each in Bootle, in St. Helens, in Preston, and in Newport, Mon.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns having an estimated population of 2,182,400 persons in the middle of this year, 1024 births and 725 deaths were registered during the week ending Jan. 20th. The annual rate of mortality in these towns, which had been 16·9 and 18·7 per 1000 in the two preceding weeks, declined to 17·3 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual rate of mortality in these Scotch towns averaged 17·6 per 1000, and was 2·4 per 1000 above that recorded in the 94 large English towns during the same period. The annual death-rates in the several Scotch towns last week ranged from 7·9 in Hamilton, 8·4 in Partick, and 9·2 in Falkirk, to 20·1 in Coatbridge, 22·0 in Greenock, and 26·4 in Ayr.

The 725 deaths from all causes in the 18 Scotch towns were 56 fewer than the number in the previous week, and included 103 which were referred to the principal epidemic diseases, against 83 and 82 in the two preceding weeks. Of these 103 deaths, 56 resulted from measles, 18 from whooping-cough, 10 from diphtheria, 9 from infantile diarrhœal diseases, 6 from scarlet fever, and 4 from enteric fever, but not one from small-pox. These 103 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·5 per 1000, or 1·6 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had been 34 and 41 in the two preceding weeks, further rose last week to 56, and included 43 in Glasgow, 4 in Greenock, 3 in Aberdeen, and 3 in Clydebank. The deaths referred to whooping-cough, which had been 13 and 12 in the two preceding weeks, rose last week to 18, of which 6 occurred in Aberdeen, 4 in Glasgow, and 2 each in Edinburgh, Greenock, and Ayr. The 10 fatal cases of diphtheria were equal to the number in the previous week, and included 4 in Dundee and 3 in Glasgow. Of the 6 deaths referred to scarlet fever, which were also equal to the number in the previous week, 2 were registered in Leith. Three of the 4 fatal cases of enteric fever occurred in Glasgow and 1 in Falkirk.

The deaths referred to diseases of the respiratory system, which had been 134 and 147 in the two preceding weeks, declined to 120 last week; and 24 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 586 births and 483 deaths were registered during the week ending Jan. 20th. The annual rate of mortality in these towns, which had increased from 18·0 to 20·3 per 1000 in the three preceding weeks, further rose to 21·8 per 1000 in the week under review. During the first three weeks of the current quarter the mean annual death-rate in the 22 Irish towns averaged 20·2 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 15·2, while in the 18 Scotch towns it was equal to 17·6 per 1000. The annual death-rates last week in the several Irish towns were equal to 25·4 in Dublin (against 14·0 in London), 20·7 in Belfast, 19·7 in Cork, 10·2 in Londonderry, 25·8 in Limerick, and 17·1 in Waterford; while in the 16 smallest of the Irish towns the death-rate last week was equal to 19·3 per 1000.

The 483 deaths from all causes in the 22 Irish towns were 33 in excess of the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against 29 and 28 in the two preceding weeks; of these 41 deaths, 19 resulted from whooping-cough, 11 from diarrhœal diseases, 3 from enteric fever, 3 from scarlet fever, 3 from diphtheria, and 2 from measles, but not one from small-pox. These 41 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; the death-rate from these diseases last week did not exceed 0·9 in the 94 English towns, while in the 18 Scotch towns it was equal to 2·5 per 1000. The deaths attributed to whooping cough, which had been 4 and 11 in the two preceding weeks, further rose to 19 last week, of which number 12 were recorded in Belfast, 6 in Dublin, and 1 in Dundalk. The deaths referred to diarrhœal diseases, which had been 6 and 4 in the two preceding weeks, rose to 11 last week, and included 9 of infants under two years of age; 4 deaths were registered in Dublin and 4 in Belfast. Of the 3 fatal cases of diphtheria 2 occurred in Dublin and 1 in Dundalk. The 3 deaths from enteric fever, the 2 deaths from measles, and the 3 deaths from scarlet fever were all recorded in Dublin.

The deaths referred to diseases of the respiratory system, which had increased from 83 to 109 in the four preceding weeks, further rose to 111 last week. Of the 483 deaths from all causes in the 22 Irish towns, 174, or 36 per cent., were recorded in public institutions, and 13 were attributed to different forms of violence. The causes of 20, or 4·2 per cent., of the total deaths in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 English towns the proportion of uncertified causes of death last week did not exceed 1·0 per cent.

THE SERVICES.

ROYAL ARMY MEDICAL COLLEGE.

Major Harold B. Fawcus, Royal Army Medical Corps, to be an Assistant Professor, vice Major C. F. Wanhill, whose tenure of that appointment has expired (dated Jan. 1st, 1912).

ROYAL ARMY MEDICAL CORPS.

Supernumerary Lieutenant-Colonel Charles C. Reilly is restored to the Establishment, vice H. C. Thurston, C.M.G., Supernumerary (dated Dec. 20th, 1911).

Major Arthur E. Thorp retires, receiving a gratuity (dated Jan. 20th, 1912).

Captain Herbert O M. Beadnell, from the Half-pay List, is restored to the Establishment (dated Jan. 17th, 1912).

Colonel S C. B. Robinson, principal medical officer of the First (Peshawar) Division from Cherat, has taken up duty at Peshawar. Lieutenant-Colonel J. M. F. Shine has arrived home on duty from India on completion of his tour of foreign service. Lieutenant-Colonel S. Hickson, on return from South Africa, has been posted to the Aldershot Command and appointed to hold charge of the Cambridge Hospital, vice Lieutenant-Colonel F. H. Treherne, who has embarked for India on promotion. Lieutenant-Colonel E. A.

Burnside, from Golden Hill, has taken up duty with the Ninth (Secunderabad) Division of the Southern Army in India. Lieutenant-Colonel C. A. Lane, at present holding charge of the Military Hospital at Hounslow, has been placed under orders to proceed to India, and on arrival will be appointed to command the Station Hospital at Madras. Lieutenant-Colonel M. L. Hearn has taken up duty as Senior Medical Officer in Ceylon in succession to Lieutenant-Colonel N. Manders, tour expired. Lieutenant-Colonel C. J. MacDonald has taken up duty as Senior Medical Officer to the Military Forces in North China, vice Lieutenant-Colonel J. M. Irwin. Lieutenant-Colonel H. J. Pocock has been transferred from Nowshera to command the Station Hospital at Sialkot. Lieutenant-Colonel B. J. Inniss, from Gravesend, has taken over charge of the Military Hospital at Belfast.

Major C. F. Wanhill, assistant professor of military hygiene at the Royal Army Medical Corps College, Grosvenor-road, has embarked for a tour of service with the Southern Army in India. Major H. P. Johnson has been transferred from Bloemfontein to the Military Hospital at Wynberg. Major J. McD. McCarthy, from Naini Tal, has taken up duty at Rawal Pindi. Major C. W. Reilly, at present commanding the Station Hospital at Dum Dum, Bengal Presidency, has been detailed as Senior Medical Officer on board the transport s.s. *Rohilla*, leaving Karachi for Southampton on Jan. 31st. Major J. P. Silver has been transferred from the Scottish Command to the Irish Command. Major H. B. Fawcus has arrived home from South Africa for duty. Major W. T. Mould, from Dover, has arrived in India for a tour of foreign service. Major W. R. Blackwell, from Lucknow, has taken up duty at Delhi. Major F. W. Begbie, from Colchester, has been granted one month's leave of absence. Major J. A. Hartigan, from Malta, has joined for duty at Tientsin. Major C. H. Straton, specialist sanitary officer, North Thames area of the Eastern Command, has been placed under orders for a tour of service in South Africa, and on arrival will be appointed Specialist Sanitary Officer.

H.E. the Commander-in-Chief in India has sanctioned one year's extension of tour of foreign service of Captain T. B. Moriarty. Captain A. F. Weston, from the Royal Victoria Hospital, Netley, has joined for duty at Jamaica. Captain C. D. Myles has been transferred from Gosport to the Military Hospital at Chester. Captain E. S. Worthington, M.V.O., has taken up duty in Canada as medical officer on the personal staff of Field-Marshal H.R.H. the Duke of Connaught and Strathearn, K.G., K.T., K.P., G.C.B., G.C.S.I., G.C.M.G., G.C.I.E., G.C.V.O., Governor and Commander-in-Chief of the Dominion of Canada. Captain E. W. Powell and Captain G. W. W. Ware have arrived home from India on duty. Captain J. S. McCombe has been granted eight months' leave of absence home from India with effect from March 1st. Captain J. E. H. Gatt, from Allahabad, has been appointed to the Station Hospital at Benares. Captain F. P. Lauder has been transferred from Youghal to Tralee. Captain J. W. S. Seccombe, on return from a tour of duty in India, has been posted to the London District. Captain E. C. Whitehead, from Edinburgh, has been appointed for duty at Glencorse. Captain B. Johnson has been transferred from the Ninth (Secunderabad) Division to Burma. Captain H. F. Shea has been appointed Specialist in Advanced Operative Surgery to the Third (Lahore) Division. Captain A. H. Heslop has been granted eight months' leave of absence home from India with effect from Jan. 31st. Captain F. A. Stephens has embarked for a tour of service in India. Captain T. H. Scott, from Jullunder, has taken up duty at the Military Hospital, Ferozopore.

Lieutenant T. H. Dickson, on completion of relief duty at Galway, has joined at Dublin. Lieutenant C. T. V. Benson, from Aldershot, has taken up duty at Deepcut. Lieutenant P. S. Tomlinson, from the Military Hospital at Tidworth, has been transferred to Bulford Camp, Salisbury Plain. The undermentioned officers have been ordered to Ireland, and on arrival will be posted as noted: Lieutenants E. S. Calthorp and R. T. Vivian to the Dublin District, and Lieutenants H. J. G. Wells and W. L. Webster to the Cork District.

INDIAN MEDICAL SERVICE.

Colonel C. F. Willis, C.B., principal medical officer of the Fifth (Mhow) Division, has taken up duty at Delhi. Lieutenant-Colonel W. R. Edwards, C.M.G., agency surgeon and chief medical officer in the North-West Frontier Province, has arrived home on one year's leave of absence from India. Lieutenant-Colonel J. M. Crawford, civil surgeon, of Benares, has been appointed to hold Visiting Medical Charge during the absence on leave of Captain H. R. Nutt.

Major C. R. Green, Bengal Presidency, has embarked for India on the termination of his leave of absence. H.E. the Governor of Bombay in Council has been pleased to appoint Major J. L. Marjoribanks, on relief, to officiate as Presidency Surgeon, Second District, Marine Surgeon, and Superintendent of the Lunatic Asylum at Colaba, in succession to Major J. H. McDonald. Major A. W. Tuke has taken up duty at Bombay Medical College as officiating Professor of Midwifery and in charge of Bai Motlibar and Sir D. M. Petit Hospitals during the absence on leave of Major S. C. Evans. Major H. Innes has been appointed Civil Surgeon at Shillong. Major J. W. D. Megaw has been granted privilege leave combined with furlough for 15 months. Major A. W. R. Cochrane, Bengal Presidency, has arrived home on leave of absence from India. Major W. Selby has been selected for appointment as Principal of the Medical College at Lucknow. The services of Major D. N. Anderson, officiating civil surgeon, have been placed at the disposal of the Government of India, Army Department. Major J. W. Cornwall has been granted combined privileged leave and furlough home from India for two years.

Captain A. G. Coullie has been appointed Specialist in Advanced Operative Surgery, Third (Lahore) Division. Captain J. W. McCoy has returned to India on the expiration of his leave. Captain W. MacKelvie, officiating civil surgeon at Darbhanga, has been granted one year's furlough. Captain F. P. Mackie, officiating civil surgeon at Fategarh, has been transferred to Bijnor. Captain H. C. Keates has relinquished charge of the duties of Superintendent of the Jullundur District Jail. Captain K. G. Gharpurey has joined for duty at Larkana as Civil Surgeon. Captain H. P. Cook has been granted an extension of his leave of absence by the Right Honourable the Secretary of State for India. Captain J. F. James has been appointed Civil Surgeon at Dhubri. The services of Captain S. B. Mehta, plague medical officer at Rohtak, have been replaced at the disposal of the Government of India, Education Department. Captain W. Tarr has been appointed a Civil Surgeon of the Second Class in the Central Provinces, vice Major P. F. Chapman, promoted First-class Civil Surgeon. Captain A. E. Grisewood has taken up duty as Plague Medical Officer at Delhi. Captain A. J. H. Russell has arrived home on leave of absence from India.

Lieutenant M. A. Rabman has been selected for appointment as Specialist in Otology, Laryngology, and Rhinology.

DEATHS IN THE SERVICES.

Brigade-Surgeon George Perry, late Coldstream Guards, at Sidmouth, on Jan. 20th, in his seventy-ninth year. He received his first commission in the army in 1855, and served in the Crimean campaign, and was present at the siege and fall of Sevastopol (mentioned in despatches). In 1882 he served with the Egyptian expedition and took part in the action of Mahuta and the battle of Tel-el-Kebir. He retired in 1888.

Surgeon-General Sir John Andrews Woolfreys, K.C.B., C.M.G., K.H.P., at his residence at Wells, in his eighty-ninth year. He entered the service in 1847 and retired in 1883. He served in the Ashanti war, 1873–74, as principal medical officer (mentioned in despatches, medal and clasp, and promoted to the rank of deputy surgeon-general). In South Africa, 1877–79, he served throughout the Galeka and Gaika rebellions, the Zulu war, and the Sekukuni campaign (mentioned in despatches).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Charles W. C. Myles is confirmed in his rank.

The undermentioned to be Lieutenants (on probation): Gilbert Malise Graham (dated Dec. 20th, 1911); and Cadet Colour-Serjeant Robert Glen Shaw, from the Edinburgh University Contingent, Officers Training Corps (dated Dec. 22nd, 1911).

TERRITORIAL FORCE.

4th Battalion, The Duke of Edinburgh's (Wiltshire Regiment): Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel Herbert P. Tayler resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Jan. 20th, 1912).

Royal Army Medical Corps.

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Major William B. Pritchard to be Lieutenant-Colonel (dated Nov. 18th, 1911).

3rd East Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant George A. Jelly resigns his commission (dated Jan. 20th, 1912).

2nd Welsh Field Ambulance, Royal Army Medical Corps: Lieutenant Henry John Dunbar, from the 3rd Lowland Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Jan. 20th, 1912).

4th London General Hospital, Royal Army Medical Corps: Major Sir Hugh R. Beevor, Bart., resigns his commission (dated Jan. 20th, 1912).

2nd Western General Hospital, Royal Army Medical Corps: Lieutenant Henry Herbert Rayner, from the 3rd East Lancashire Field Ambulance, Royal Army Medical Corps, to be Captain (dated Jan. 20th, 1912).

For Attachment to Units other than Medical Units.—Surgeon-Captain Robert John Richard Cobden Simons, from the Glamorgan Royal Garrison Artillery, to be Captain (dated Jan. 20th, 1912).

Unattached List for the Territorial Force.—Captain Henry Wade (serving with the Edinburgh University Contingent, Senior Division, Officers' Training Corps) resigns his commission (dated Jan. 20th, 1912).

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force, who have been duly recommended under the terms of the Royal Warrant dated August 17th, 1908:—

4th (Cumberland and Westmorland) Battalion, The Border Regiment: Surgeon-Major William Symington.

Royal Army Medical Corps.

1st Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant Colonel William Francis Somerville. 1st Eastern General Hospital, Royal Army Medical Corps: Colonel Joseph Griffiths.

SOLDIERS' RATIONS.

The War Office has decided that the diet of soldiers may be varied at the discretion of commanding officers by the issue of rabbits in lieu of fresh beef once a week, provided that any extra expense is made good regimentally. A somewhat similar variation was tried last year when fresh pork was offered instead of fresh beef.

Correspondence.

"Audi alteram partem."

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—There cannot be the least question of the great resentment of the medical profession at the way in which this measure has been introduced, and the light way in which the vital interests of the profession have been spoken of by politicians. Such resentment is perfectly natural, but there is undoubted danger lest the feeling of irritation should blind the eyes of the members of the profession to the real facts of the situation. Many seem to be acting and arguing as if we were dealing with a Bill instead of an Act, and others seem to forget that the Act is a very different thing from the Bill which was introduced, thanks to the determined attitude taken by members of the profession in all parts of the country. We have not gained all we wanted, but we are standing to lose even that which we have gained unless we set ourselves to understand the Act and leave no stone unturned to obtain for the profession conditions under which alone it is possible to give an efficient medical service to the poorer classes of the country and at the same time to do justice to the profession.

There is another point also which seems to be overlooked. Contract practice as now carried on is an evil of the greatest magnitude, and involves an injustice to the profession which can hardly be over-estimated. There seems to be a possibility at the present moment of righting some of these wrongs if the profession resolutely act together. Therefore it is of the utmost moment that we should get together for business discussions and leave aside mutual recriminations. It seems to me that one mistake which is being made is the failure to recognise the different issues with which we have to deal at the present moment, and I would like to distinguish these by the two expressions, *Terms* and *Tactics*.

(1) We want, on the one hand, to find out what are the *Terms* under which the medical profession will accept service under the Insurance Act. It will no doubt be replied that our terms are the six cardinal points, but these need to be greatly elaborated before they can be brought to any practical issue. We claim that "the method of remuneration" should "be according to the majority of the members of the medical profession in any particular district," and the "method of remuneration" is to be what the medical profession considers adequate. But the question is, What method of remuneration will the profession demand? Is it to be a capitation fee, or payment for work done? And again, in either contingency, what payment is to be regarded as adequate? It is such problems as these that ought to engage the earnest attention of every body of medical men all over the country, for it is useless for us to abuse either the Government, or the Insurance Commissioners, or even the Friendly Societies if we do not know what we want under these heads. I suppose that the result of inquiries will show that the members of the medical profession in different areas desire different methods of remuneration, and that therefore we shall have to come to the system laid down in the Act—viz., that of local option in each district.

(2) Turning now from the question of *Terms* we come to the question of *Tactics*, and it is under this head that I should like to make some special comments.

(*a*) We ought to realise, in the first place, that very large powers have been given to the Insurance Commissioners, and this is very clearly shown in the pamphlet, "A Guide to the Insurance Act," by Mr. Thomas Smith, reviewed in your columns last week. He says:—

> So wide are the powers conferred upon the Commissioners by the Act, that it is hardly an exaggeration to say that they themselves are empowered to make a new Act of Parliament. The framework of the scheme is, admittedly, contained in the Act under consideration, but upon the regulations to be drawn up by the Commissioners will depend the success or failure of the measure in its daily construction and administration.

No one can doubt the truth of this statement who has seriously studied the Act. If, then, this is the case there is surely no time to be lost, first in agreeing as to the regulations which we should like the Insurance Commissioners to frame, and then in bringing all possible pressure to bear to obtain these. I have no doubt that the central authorities of the British Medical Association are doing their best to consider these points, but if they are to meet votes of censure and to spend their time in replying to hostile criticisms concerning incidents which are now matters of history, we may lose the great opportunity which we now have. I have heard some indignation expressed because apparently some representatives of the Friendly Societies have had a conference with the Insurance Commissioners. The fact is that these men are masters of *Tactics*, and if we want to get justice for our cause it would be well for us to take a leaf out of their book.

(*b*) The next point of importance in my opinion consists in utilising the power to form Local Medical Committees, and I am inclined to think that the clause of the Act which deals with this is the pivot upon which the power of the medical profession under the Act is to be exercised. If the medical practitioners in each locality act together on such a committee, and there are no splits, and if the various Local Committees act in concert with one another, then the future of the Insurance Act lies in our hands, for we can now dictate our terms. It is quite true that it may be some time before the Local Insurance Committees can be formed with which these local medical committees could be brought into contact, but we want to anticipate the formation of these committees, and to be ready with our nominees to represent us on these committees and to arrange the terms upon which the local profession would be willing to act. These medical committees will have a big task before them, and there is no time to be lost in getting together for this purpose. Of

course, no panel must be formed anywhere until the rightful terms of the profession are accepted all over the country, but we shall not compromise our position by forming the local medical committees.

(c) Much objection has been raised to the Act because of the inadequate representation of the medical profession on the various administrative bodies, but I think that with local Medical Committees safeguarding the interests of the profession it will only be necessary to have representatives on the committees. I believe that it will be difficult to get general practitioners to devote the time which will be involved in filling the posts now open to medical men on these committees, and it is a mistake to think that medical men could be found in large numbers to give the time that will be required to attend to the detail of these insurance committees.

I trust that these matters may be taken into the most careful consideration. I am, Sir, yours faithfully,

Leyton, E., Jan. 22nd, 1912. CHARLES F. HARFORD.

To the Editor of THE LANCET.

SIR,—I am sure my friend Dr. Major Greenwood will forgive me for not at present entering further into the controversy concerning the merits of the *per capita* or per attendance systems of payment for medical service. He and I are well aware how impossible it is to induce the enthusiasts for either method to look favourably upon the other. We both took part in formulating the compromise which is embodied in the "local option" clause as to method of remuneration amongst the so-called six cardinal principles, and I am sure neither of us desires to interfere in any way with that compromise or to do anything that might for a moment be regarded as a weakening of the profession's attitude towards its six-point programme.

My recent intervention in your columns and elsewhere has been entirely due to the fact that two influential members of the profession, no doubt in ignorance of the difficulty with which the compromise had been arrived at, had written urging upon their colleagues a course which, if persisted in, must lead to the abandonment of one of the cardinal principles and cause serious dissension in our ranks. Until "local option" as to method of remuneration is firmly established in the Commissioners' regulations it is unsafe for the medical profession to reopen their discussions on the merits of the respective systems.

I am, Sir, yours faithfully,

Jan. 22nd, 1912. LAURISTON E. SHAW.

To the Editor of THE LANCET.

SIR,—It is with great dismay that I note so little protest is made concerning our independence, the most important point of all, under the Insurance Act. As the Act stands three-fifths of the Local Insurance Committee is composed of members of Friendly Societies and Post Office contributors; thus, technically, this seems to satisfy one "cardinal point"; but as a matter of actual practice and in effect is it not clearly evident that we are as badly off (or worse) as if we were entirely under the control of Friendly Societies? This point the council of the British Medical Association, if it claims to represent the profession, must immediately and definitely insist on being rectified.

Surely the silence of the Friendly Societies on this point speaks volumes, for they know full well that if we are fools enough to work under the Act without a drastic alteration on this particular point at least, no matter what our remuneration may be, they will be able to dictate to us. The newspapers may be full of accounts of medical men being hauled up before these tribunals. Are we content, on matters of discipline, to be subject to such bodies with only a right of appeal to the Commissioners? Surely the deciding body should be the General Medical Council.

Can anyone expect any self-respecting father to permit his son to enter our profession where service under such debasing conditions exists? I believe this Act to be the "beginning of of the end" for our profession as an honourable calling.

I am, Sir, yours faithfully,

Manchester, Jan. 22nd, 1912. E. T. LARKAM.

RETROGRADE SANITATION.

To the Editor of THE LANCET.

SIR,—In spite of the pressure of other business, last Session the Government found time to pass a "Factories and Workshops Act," 1911, and Mr. McKenna has just issued some "Regulations as to Humidity and Ventilation in Cotton Cloth Factories" (Statutory Rules and Orders, 1911, No. 120). It is headed "Health and Safety," but after careful perusal it is only safe to conclude that those portions of these regulations relating to ventilation can but tend to deterioration in the health of the operatives.

It is true that these rules contain certain orders relating to humidity and the care of clothes, which had been previously in force, but which are now dealt with in more detail and with greater definiteness of language than had been done in previous regulations, and this is truly an excellent thing. When, however, it is seen that, in reference to ventilation, the standard of purity of the air is greatly reduced, the conclusion will be reached that a grievous mistake (or I would rather say a crime against the laws of health) has been thereby committed.

In Regulation 9 of this document it is enacted that "In every *humid shed* and in every *dry shed* the arrangements for ventilation shall be such that at no time during working hours shall the proportion of carbon dioxide in the air, in any portion of the shed, exceed the limit specified below for that shed, namely:—

for *humid sheds* 8 } parts by volume of carbon dioxide per 10,000 of air
for *dry sheds* 11 } in excess of the proportion in the outside air at the time.

Now, in the regulations previously in force the amount of carbon dioxide allowed per 10,000 volumes of air had only been five volumes in the case of humid sheds, and the same standard was recommended by the then Home Office Committee for dry sheds as well. It will therefore be seen at a glance how great a fall in the purity of the air in all these sheds will follow this enactment. The history of the last-named standard is briefly as follows.

In the year 1896–97 a Home Office Committee was appointed to inquire into the conditions of humid sheds. It consisted of Sir H. Roscoe, F.R.S., the late Sir William Roberts, F.R.S., and myself, and among other matters requiring attention we found that the amount of ventilation in these workplaces required by statute was insufficient. In our report to the Home Office we therefore recommended that as a measure of the respiratory impurity no greater proportion than nine volumes of carbon dioxide per 10,000 volumes of air (i.e., five volumes more than was contained in the outer air) should be allowed in the sheds, and that the ventilating arrangements should be sufficient to secure the general attainment of this standard. We pointed out that "this limit will secure an amount of ventilation corresponding to about 2000 c.f. per head per hour, and your committee believe that such a requirement would bring about a material improvement in the health and comfort of the workers." This proposal was accepted without protest by both masters and workpeople.

Two years later, in 1899, Mr. Williams, the inspector under the Cotton Cloth Factories Acts, noted that "the scientific tests had already led to a great improvement in the working conditions of the operatives, and that it had also done much to promote an intelligent interest and a more exact knowledge on the subject of ventilation." He also drew up the following table showing the results before and after the improved means of ventilation had been installed.

Table showing Approximate Number of Volumes of Carbon Dioxide per 10,000 due to Respiration.

Before improvements.	After.	Before improvements.	After.
8·0	3·1	9·2	3·8
6·8	4·2	11·	3·6
10·7	3·1	7·7	2·4
11·3	2·6	10·4	3·7
6·9	3·0	7·8	2·4
9·0	4·2		

Mr. Williams further remarked that the health of the operatives had greatly improved and the sickness-rate had been much smaller.

All the evidence drawn from public health annals shows that this final result of improved ventilation is only what

might have been anticipated, and I greatly fear that the new and degraded standard will lead to more ill-health, to respiratory disease, and especially to an increase in the number of consumptives.

I am, Sir, yours faithfully,

Bournemouth, Jan. 22nd, 1912. ARTHUR RANSOME.

INTESTINAL MYIASIS.

To the Editor of THE LANCET.

SIR,—The addition of a few references to Dr. E. A. Cockayne's bibliography in his interesting paper on Intestinal Myiasis would make it more complete. I have seen five such cases in infants, in four of which the larvæ were present in the stools and in one they were found in the vomit. The particular varieties were not identified.

I am, Sir, yours faithfully,

Park-street, W., Jan. 23rd, 1912. EDMUND CAUTLEY.

Additional bibliography.—1. Cohn: Deutsche Medicinische Wochenschrift, March 24th, 1898; age 3 months; larvæ in vomit and fæces. 2. Keenan: THE LANCET, 1903, vol. i., p. 200; infant; larvæ in vomit. 3. S. M. Lawrence: Brit. Med. Jour., 1910, vol. ii., p. 376. 4. A. E. May: Brit. Med. Jour., 1906, vol. ii., p. 180. 5. A. B. Northgate: Brit. Med. Jour., 1906, vol. ii., p. 180. 6. J. Smyth: THE LANCET, 1902, vol. ii., p. 1487. The last four cases consisted of a girl, 9 years old, and three males, an adult, a boy, and an infant with larvæ in the stools.

To the Editor of THE LANCET.

SIR,—Dr. E. A. Cockayne in his interesting article in THE LANCET of Jan. 20th on "Intestinal Myiasis" says: "There is still a little doubt as to how the larvæ gain access to the intestinal tract," and then mentions various articles of food, among which milk is conspicuous by its absence. I have on several occasions observed that the ovipositor of a fly drowned in milk has been extruded, and I have little doubt that the eggs were in the milk, though I did not search for them. I have recorded observations that when temperature conditions were favourable, *fermentation* of food stuffs was not an essential factor in the growth of the larvæ of the house fly. In cases of intestinal myiasis the eggs or young larvæ might easily be introduced in milk from which a drowned fly has been removed—a not infrequent incident in many homes in the "fly" months.

Flies will live through the winter in a warm kitchen or bakehouse, and milk is frequently kept in such places. The colour of the milk prevents the ova or larvæ being observed without careful straining and minute examination. Even the extraordinary cases in which larvæ have been passed for months or years may also thus be explained.

I am, Sir, yours faithfully,

Norwich, Jan. 20th, 1912. J. T. C. NASH.

SENSORY DISTURBANCES AND CEREBRAL LESIONS.

To the Editor of THE LANCET.

SIR,—Among the many conclusions arrived at by Dr. Henry Head and Dr. Gordon Holmes in their studies of the sensory disturbances resulting from cerebral lesions,[1] I find none more interesting than that which assigns to the optic thalamus, or rather the "essential organ" of this structure, a leading rôle in the genesis of feeling (affective) tone. This element of feeling tone not only enters largely into the massive sensations of pleasure and discomfort, but also into emotional feelings, such as fear, joy, anger, gloom; it constitutes, moreover, the essential ingredient of mental temperament and of moods.

The suggestion that feeling tone is largely determined by the activity of a limited portion of brain tissue may to some appear somewhat startling. When, however, we call to mind that a creature with a brain no larger than a pea, such as a mouse or small bird, is capable of as highly developed affective tone as man himself, it becomes evident (1) that a diminutive mass of brain tissue suffices for the genesis of affective tone; and (2) that the enormous development of the cerebral hemispheres in the higher mammals is not for the purpose of adding to feeling capacity in its grosser aspects, but, on the contrary, is essentially bound up with intellectual development—a conclusion, needless to say, in entire harmony with the views of Dr. Head and Dr. Holmes as to the rôle which the cerebral hemispheres play in sensation.

The identification of feeling tone with the optic thalamus helps us to understand the anatomico-physiological mechanism pertaining to moods and mental temperament. If these depend, as they undoubtedly largely do, on feeling tone, and if feeling tone is closely associated with the activity of the optic thalamus, then moods and temperament must be closely dependent upon the activity of this organ. Now feeling tone is profoundly influenced by the state of the blood (witness the change in the affective nature during the rutting time, and as the result of the action of such substances as alcohol and morphine), and we therefore seem justified in assuming that temperament and moods depend in large measure upon the manner in which that subtly complex and ever-changing fluid, the blood, plays upon a particular part of the mind instrument—to wit, the optic thalamus.

I may here remark parenthetically that there is strong evidence in favour of the conclusion that differences in mental temperament essentially depend, not upon differences in brain organisation, but upon differences in blood composition; not upon differences in the structure of the mind instrument, but upon differences in the way that instrument is played upon by the blood.

May I, Sir, in conclusion suggest that the authors of these remarkable articles might throw still more light on a subject they have done so much to illuminate, by investigating the effects on the various forms of sensibility of substances such as alcohol and morphine?

I am, Sir, yours faithfully,

Wimpole-street, Jan. 20th, 1912. HARRY CAMPBELL.

NON-TUBERCULOUS MILK IN GUERNSEY.

To the Editor of THE LANCET.

SIR,—The recent report of the Royal Commission upon Tuberculosis has called attention to the fact that a large proportion of the tuberculosis of children and young people is due to the consumption of milk from cows affected with this disease. Until 1906 tuberculosis was apparently unknown amongst Guernsey cattle, but it was then introduced by cattle re-imported after having been to England for exhibition. This re-importation is now forbidden, and drastic laws have been passed compelling the slaughter of all infected cattle and granting State compensation. As a result the disease has been practically stamped out, and of the 1364 animals exported during the past three years, all of which were tested with tuberculin, only six were found to be affected. This gives tuberculosis a rate of under ½ per cent. compared with the estimate of Sir John McFadyean, principal of the Royal Veterinary College, London, of 20 per cent. of adult cows in England.

The forms of human tuberculosis chiefly caused by bovine tuberculosis (tubercular glands of neck, abdominal tuberculosis, and lupus) are consequently exceedingly rare in the island of Guernsey. Channel Islands' cows give the richest milk in the world, the average of fat for Guernsey cattle being over 60 per cent. above the English legal standard for fat. It is impossible to over-rate the importance, especially where children and delicate persons are concerned, of milk so rich in butter fat, and above all so free from the germs of the scourge of tuberculosis.—I am, Sir, yours faithfully,

HENRY DRAPER BISHOP,
Medical Officer of Health, States of Guernsey.

Health Office, Guernsey, Jan. 20th, 1912.

THE FINSBURY MEDICAL SOCIETY AND TUBERCULOSIS DISPENSARIES.

To the Editor of THE LANCET.

SIR,—At a meeting of the Finsbury Medical Society held on Friday, Jan. 19th, the following resolution was unanimously passed:—

That the Finsbury Medical Society presents strenuous opposition to the establishment of a tuberculosis dispensary in Finsbury on the lines proposed by the Central Committee for the Establishment of Tuberculosis Dispensaries.

I am, Sir, yours faithfully,

W. FRANCIS ROE, Hon. Sec.

Northampton-square, E.C., Jan. 20th, 1912.

PSYCHOTHERAPY AND GENERAL MEDICINE.

To the Editor of THE LANCET.

SIR,—I have read with much interest Dr. W. P. S. Branson's paper in THE LANCET of Jan. 13th, p. 92, on "Psychotherapy and General Medicine." But I cannot help thinking that whilst he has done a good service by drawing attention to a much neglected branch of medicine, he has, unwittingly, no doubt, minimised the rightful position of psychic treatment in therapeutics. In the first place, Dr. Branson has confined himself to that simple form of psychotherapy which consists mainly of prolonged conversations with patients, in which persuasion and optimistic affirmations find a conspicuous place. This is a method which is most certainly well adapted to the uses of the general practitioner, as Dr. Branson points out, but unquestionably owes much, if not all, of its success to the principle of "suggestion." Professor Dubois and others have eloquently endeavoured to differentiate "persuasion" from "suggestion," and in theory one can no doubt do so. But when it comes to a matter of practical application, who can truthfully say that the forcible "conversation" of the kind in question, with its optimism, its confidence, and its reiterated affirmations of future well-being, is not, indeed, an example of the method of treatment by suggestion in the waking state? It is, in fact, a form of direct suggestive influence that has brought success to many an understanding doctor, and was in use centuries before Dubois clothed its description in imposing psychological terms.

Now it is a common-place among those who have had extensive experience of psychotherapy that whilst this conversational method of suggestive therapeutics is found to be successful in numbers of "easy" cases, there are many that are quite unrelieved by it—as Dr. Branson quite rightly acknowledges—and for these "difficult" cases more direct methods of psychic treatment are well known to be successful. In the face of this it is surprising that Dr. Branson should stigmatise "all forms of bald suggestion" as "pure chicanery," for the understood meaning of that phrase, as may be seen on reference to any good dictionary, is some shifty artifice or trickery.

When Dr. Branson further says that, in contra-distinction to the methods of direct suggestion, "rational psychotherapy, on the other hand, attempts to discharge the pathogenic notion by an appeal to the reason," he is surely dealing with psycho-analysis, in which the morbid idea is first unearthed and then "discharged." His conversational method of carrying this out as compared with the proper technique employed by psychotherapists to-day is unscientific and necessarily uncertain, and so scarcely "rational." Let it be understood by all means that the conversational method of benefiting patients by suggestion can be a most important adjunct to routine treatment ready to the hands of every medical practitioner; let every effort indeed be made to demonstrate its advantages to the profession at large. But do not let us elevate this method beyond its due position. To say that the so-called "rational psycho-therapy" as described by Dr. Branson is immeasurably superior to all direct methods, when the former is actually based on the influence of active verbal suggestion, and at the same time contains a proportion of arm-chair psycho-analysis, is to say that parts may be greater than the whole.

There is just one more point in connexion with the part unquestionably played by direct suggestion in Dr. Branson's method, and it is this. That writer asserts that he has not been as successful as he expected to be in its use; presumably, therefore, not as successful as Dubois himself. This experience is paralleled in regard to many psycho-therapeutic methods in which the generality of investigators have been unable to reproduce the success of a few others. It is a recognised condition of things that can only be explained—unsatisfactorily enough, to be sure—by saying that "personality" makes all the difference between success or failure in psycho-therapy. And it must be remembered that Professor Dubois happens to be a man of tremendous personality. Can it be doubted that the "driving-force" inherent in such a personality is not always to be found ready to hand in the case of everyone else. The factor of "personality" seems to be the crux of the whole matter.

Apropos I am reminded of a recent review in your columns of a book on suggestive therapeutics in which, referring to the author's opinion that the man behind the method is of more importance than the method itself, the reviewer commented that "it would be interesting if ..... someone ..... would try to express scientifically just wherein the differences between the successful and the unsuccessful practitioner—i.e., of psychotherapy—consist."[1] This is, of course, one of the most difficult problems to be met with in attempting to formulate hypotheses which will reasonably account for the phenomena of psychic treatment.

The value of Dr. Branson's paper is unquestionable, but it seems a pity that in advocating the particular psychic method which he himself has worked with, he should lend the weight of his name to condemning other methods of which, from the practical point of view, he can have had little experience as compared with those who devote the greater part of their time to them.

I am, Sir, yours faithfully,

Seymour-street, W., Jan. 18th, 1912. EDWIN ASH.

THE PREVENTION OF TUBERCULOSIS: A CORRECTION.

To the Editor of THE LANCET.

SIR,—Writing from the Galton Eugenics Laboratory Dr. David Heron has kindly drawn my attention to certain matters which seem to require correction. In my article on the Prevention of Tuberculosis published in THE LANCET of Jan. 6th I referred to certain statistics on the physical condition of school-children which I obtained from a report presented by Mr. Culpin. It would appear that these statistics were originally brought forward by Dr. Leslie Mackenzie and Captain Foster published by the Scottish Education Department. Dr. Heron informs me that "in getting the averages boys of all ages were lumped together. When correction is made for age, instead of boys from one-roomed houses being 11·7 lb. lighter and 4·7 in. smaller than boys from four-roomed houses, these differences become 5·5 lb. and 2·4 in. The explanation of this marked change is that among boys from one-roomed houses only 2·4 per cent. are aged 14 and upwards, while among boys from four-roomed houses the percentage is 11·9."

Allowing for this correction would therefore make the statistics from the point of view of my argument less striking than the uncorrected figures. On the other hand, as the result of an error in transcription the ages of the children were given by me as from 15 to 18 instead of from 5 to 18, and a difference of 2·4 in. and 5·5 lb. would be more remarkable in children of an average age of 11·5 years than if the children referred to had really been of the average age of 16·5. I am, Sir, yours faithfully,

Harley-street, W., Jan. 20th, 1912. J. SIM WALLACE.

A CASE OF FATAL HÆMOPTYSIS IN A BABY 13 MONTHS OLD.

To the Editor of THE LANCET.

SIR,—Dr. Ralph Brown, in THE LANCET of April 30th, 1910, reports as uncommon a case of fatal hæmoptysis in a child 3 years of age. I wish to record a case of fatal hæmoptysis occurring in a baby 13 months old. I attended at the birth of this child on May 5th, 1910. Labour was natural, the mother delivering herself. No consumption in either father's or mother's family as far as is known. The child was quite healthy up to Feb. 9th, 1911, when he developed broncho-pneumonia of both lungs accompanying measles and was extremely ill. I saw him three or four times a day for about a fortnight. Up to March 15th I saw him daily, after which date I attended irregularly till April 13th. The child made a fair recovery from the broncho-pneumonia. He never really got over it so well as I would have wished on account of the mother's carelessness. When I asked her to take the child out into the air she either went into a neighbour's house or kept him out until he was blue with cold. I did not see the child from April 13th to May 22nd. During the interval he had been anything but well, the mother neglecting to let me know the condition of the child.

[1] THE LANCET, Jan. 21st, 1911.

On the evening of May 21st I saw the father, who asked me to call on the following day, which I did, and was much surprised to find the child in a very serious condition. The lungs were in a terrible state. Nothing could be done for the suffering mite. I attended every day, doing my best to relieve the child, but he gradually grew worse and on May 29th, while on my rounds, I was met and asked to see the little patient at once as he was vomiting blood. I accordingly hurried to the house, only to be met with the cry that the child was in a neighbour's house. The mother, when she saw the blood, screamed, and ran and threw the baby into the lap of a neighbour. The child had given a very slight cough, when blood began to flow from mouth and nose. He vomited three times within the hour, in all about 3 to 4 ounces. There was no blood vomited from 12 noon to 4 A.M. on the 30th, when vomiting again commenced, the vomit being only coloured with blood at the time. About 9 30 A.M. he had another attack of vomiting, about one ounce of blood at this time. There was no more vomiting till 12.50 P.M., when he vomited about three drachms of blood with fatal result. Treatment was confined to staying the blood if possible, cold water, ice, with adrenalin and ergot. There was no necropsy.

Can any of your readers let me know how frequently hæmoptysis occurs in so young a child?

I am, Sir, yours faithfully,

P. CARRUTHERS WATT, L.R.C.P. Edin., &c.

Gatehouse of Fleet.

THE DETERMINING FACTOR IN SEX.

To the Editor of THE LANCET.

SIR,—Professor Ciesielski of Lwow has after 30 years' hesitation published a short pamphlet in Latin giving the result of experiments in the production of sex. He is a botanist, and his initial experiments were on plants. Naturally a dicœcious plant had to be employed; most dicœcious plants produce occasional staminal flowers on female individuals, but such a "sport" occurs with extreme rarity in *Cannabis sativa*, and accordingly this species was chosen for experiments. Professor Ciesielski concluded, as far back as 1878, that the determining factor is the freshness or otherwise of the pollen cell. His first conclusive experiment gave 94·6 per cent. of male plants in the case of artificial impregnation with pollen from an anther which was just dehiscing, and 100 per cent. of female plants when the pollen had been kept some 12 hours before use. The experiment was several times repeated with similar results.

He thereafter investigated the question in the animal kingdom. The conditions of experiment being less fully under the control of the investigator, the results are not so striking, but they are numerous enough and consistent enough to deserve attention. His statement of the law governing sex is as follows:—

Pari modo in animalibus et hominibus destinari tantum zoospermiis sexum orituri fetus. Zoospermia enim recentiora (i.e., ducentia originem ex ejaculatione spermatis masculini, quae fit ante decursum spatii unius diei ab antecedente coitu) producere fetum masculum, zoospermia autem vetustiora (quae ejaculata sint post longius spatium quam unius diei ab antecedente coitu) prodere fetum femineum.

He made experiments in rabbits, in dogs, horses, and cattle. Of these the first two were not very striking; but he declares that careful analysis of the stud record of a stallion showed that the rule held generally in regard to female foals and invariably in the case of male foals. With a stud bull under the control of an intelligent and careful servant of his own he found only two exceptions to his rule in 156 cases, and he believes these to be only apparent exceptions.

Denique non est silentio prætereundum, mihi per triginta tres annos sæpius potestatem ejus legis in hominibus probandæ non defuisse, consultus enim a multis meis cognatis, amicis, familiaribus præcepta idonea dabam, quæ quotiescunque observata erant diligenter, prosperos eventus habebant.

Many investigators have believed they had solved this problem; very few, one fancies, have maintained a firm belief in their solution for 30 years, and yet not published it. Professor Ciesielski deliberately kept his solution to himself, "verebar enim, ne cognita ad depravandos rectos mores conferret," and has now deliberately enshrined it in this brief Latin pamphlet of 15 pages. The law is so simple, depending on a single factor, and is stated so definitely by him, that confirmation or disproof of its truth ought to be obtained without much difficulty by other observers.

I am, Sirs, yours faithfully,

Norwood, Jan. 22nd, 1912. S. W. CARRUTHERS, M.D. Edin.

THE MORBID DIATHESES.

To the Editor of THE LANCET.

SIR,—Sir Dyce Duckworth has done good service in drawing attention to this now unfashionable but vitally important subject; perhaps you will allow me slightly to elaborate it. The "constitution" includes all the intrinsic tendencies, normal and morbid, of the individual; a "morbid diathesis" is a particular, recognisable constitutional defect. These morbid diatheses, or constitutional defects, are just as effective in causing symptoms of disease as are microbes, and far more ubiquitous. If we consider four individual patients, a diabetic child, an asthmatic man, a hysterical young woman, and a *bonâ fide* chronic lunatic, it will be acknowledged, even by surgeons and bacteriologists, that the symptom-groups shown are not due to any "extraneous influence," to any extrinsic cause. In these and many other cases the symptoms are due to a morbid diathesis, to a cause of purely intrinsic origin.

Each of these patients is an example from a series of cases, a "known series" in our science. From each such series we may, if we will, derive a conception that will in each case represent a true disease. "The diseases" diabetes, asthma, hysteria, insanity, would thus become "diseases of intrinsic causation." They would correspond with, for instance, typhoid fever, lead poisoning, and heat-stroke, these latter being conceptional diseases of extrinsic causation. It will no doubt interest Mr. Clement Lucas to hear that his old friend Dr. Walter Moxon said, in his introductory lecture in 1884: "The causes of disease have been divided in the past into predisposing and exciting; they will be divided in the future into intrinsic and extrinsic." Dr. Moxon was before his time, but he was no false prophet.

I am, Sir, yours faithfully,

Clevedon, Jan. 22nd, 1912. SYDNEY W. MACILWAINE.

THE ADMISSION OF VENEREAL CASES TO GENERAL HOSPITALS.

To the Editor of THE LANCET.

SIR,—In the paper on Venereal Diseases[1] by Dr. D. White and Lieutenant-Colonel C. H. Melville it is suggested that patients suffering from them should be admitted to general hospitals, that special arrangements and wards should be provided for these cases, and a special course of instruction should be given to the medical staff as to the diseases and their treatment at the State expense. The nursing, however, has not been considered, and a special staff of trained male and female nurses would have to be provided and maintained. The need for male nurses for such male patients needs no demonstrating, especially in the hospitals without medical schools, where there are no dressers to give injections and to do the dressings, unless the patients are to carry out the local treatment themselves.

A well-paid staff of trained women would also be requ red, for it would not be justifiable to force young probationers to nurse in the venereal wards as part of their training in order to gain their certificate. Nurses who enter small-pox hospitals or volunteer as plague nurses do so with full knowledge of the risks they run. The ordinary well brought up girl of from 20 to 25, the usual age at which probationers enter hospitals, is ignorant of the existence of venereal disease and of the horrible consequences of contracting it, and certainly should not be exposed under compulsion and in ignorance to such a vile contagion. It has been said that students and doctors run the same risk. But young men are not brought up in ignorance of these diseases as their sisters are, and they are fully aware of their dangers; also the risk incurred in a daily visit to the wards and the performance of dressings and examinations with every precaution against infection is a very different one from that incurred by the nurse. For she has to live all day and every day from 7 in the morning to 9 at night (except for two off duty hours and meal times) in the offensive atmosphere of a

[1] THE LANCET, Dec. 9th (p. 1615) and 16th (p. 1692), 1911.

ward of syphilitic patients, during which time she is constantly performing details of nursing which bring her into contact with infectious discharges and which in many cases it is not possible to carry out with the gloved hand.

The mental as well as the physical atmosphere must be considered, and the forced daily companionship of fallen and vicious women is a strain entirely unsuitable for a young probationer to be subjected to. No real nursing can exist where the patient's personality is treated as non-existent and the area of disease alone is considered. You cannot nurse the disease and ignore the patient suffering from it; mind and body are too interdependent. It is difficult for a young girl to overcome the horror and repulsion following the knowledge of sexual vice and its results, and to feel anything but disgust for its victims. Older and more experienced women while retaining their loathing for vice can at the same time feel profound pity and the desire to raise the fallen. The "intolerance of youth" has merged into the realisation that, at all events sometimes, *tout comprendre, c'est tout pardonner*, and that hatred of sin may coexist with tenderness and help for the sinner. So for the patients' sakes, as well as for the probationers, a staff of specially qualified women would be needed to undertake nursing of venereal cases in the female wards and in the out-patient department if such cases were admitted to general hospitals.

I am, Sir, yours faithfully,

Jan. 15th, 1912. A HOSPITAL MATRON.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

THE annual report of the University of Edinburgh for 1911 shows that during the year the total number of matriculated students (including 630 women) was 3421. Of these, 1353 (including 19 women) were enrolled in the faculty of medicine. Of the students of medicine 593, or nearly 44 per cent., belonged to Scotland; 265, or nearly 20 per cent., were from England and Wales; 91 from Ireland; 99 from India; 256, or nearly 19 per cent., from British colonies; and 49 from foreign countries. The following medical degrees were conferred during 1911:—M.B., C.M., 1; M.B., Ch.B., 164; M.D., 72; and Ch.M., 2. The diploma in tropical medicine and hygiene was conferred on 9 candidates.

Edinburgh Royal College of Physicians: Annual Dinner.

This dinner was held on Jan. 19th, in the hall of the College, the chair being occupied by the President, Dr. Byrom Bramwell. The toast of the City of Edinburgh was responded to by the Lord Provost; the Houses of Parliament by the Secretary for Scotland, Lord Pentland, and by the Lord Advocate, Mr. Ure. The toast of the College, proposed by the Earl of Aberdeen, was responded to by the President.

Glasgow's Unhealthy Areas.

Dr. A. K. Chalmers, medical officer of health of Glasgow, has prepared a report on insanitary buildings in congested areas in Glasgow. He points out that in eight wards the annual death-rate always exceeds that of the city; in eight other wards the rate is occasionally above the city rate; while in the ten remaining wards the rate is always below the general average. Attention is directed to the internal defects met with in the older class of houses. The most frequent of these are common lobbies deficient in light and ventilation, which can now be dealt with under the Buildings Regulation Act; and concealed beds, which are prohibited in new buildings and illegal in existing houses. Another very serious defect is where "houses" are functionally back to back, although contained in the same tenement. This occurs when one apartment enters through another, and the windows of both are in the same external wall. This feature is almost characteristic of the older two-apartment houses in Glasgow, and it presents the same difficulty of through ventilation as gained notoriety for the back-to-back houses in England. The Housing and Town Planning Act of 1902 prohibits the erection of back-to-back houses in separate buildings, while allowing it in tenements if the medical officer is satisfied that they are so arranged as to secure effective ventilation of all habitable apartments. As a result of the operations carried on under the City Improvements Act, 1897, there have been cleared away from congested areas 773 houses. Under the Glasgow Police Amendment Act 918 houses have been closed as unfit for habitation, and 1539 have been closed under the Housing of the Working Classes Act, making a grand total of 3228 undesirable houses closed. Under the Building Regulations Act it was intended to secure that there should be proper restriction of the kind of building to be erected on any area of ground enclosed by a continuous wall of tenements and that due provision was made for ventilating the space. This applied only to new buildings, and the problem has been how to get rid of such as already existed. Dr. Chalmers suggests that the provision of open spaces on the margins of overbuilt areas fails to accomplish as much for the population as would be done by enlarging the intervals between the tenements. He suggests that the corporation should set aside a sum annually for reforming the worst areas. The report is accompanied by another from the town clerk detailing the statutory powers already available for the handling of these problems.

A Scottish Medical Insurance Council.

After weeks of difficulty and of delicate negotiations Scotland is now within sight of the formation of a central council for the purpose of dealing with the medical questions arising out of the Insurance Act. The aim has been to make this projected council representative of all the medical interests in Scotland—the Universities, the Medical Corporations, and of course the British Medical Association, as it is officially recognised in Scotland through the Scottish Committee of the Central Council of the Association. On Saturday, the 20th inst., a conference called by the Medical Corporations was held in the Royal College of Surgeons. It was attended by members of the Councils of the Corporations, by three representatives from Edinburgh and Aberdeen Universities, by two or more from Glasgow University, while St. Andrews sent a letter expressing sympathy with the movement and regretting that owing to another engagement no member of the Senate could be present. It was also attended by all the members of the Scottish Committee of the British Medical Association, of which Dr. Michael Dewar is chairman, and Dr. G. R. Livingston, of Dumfries, secretary. The chair was taken by the President of the College of Surgeons, Dr. G. A. Berry, on the motion of the President of the College of Physicians. After a good deal of discussion it was decided that joint action was desirable, and that steps should be taken to form a Scottish Medical Insurance Council, to consist of representatives of the four Universities, the three Medical Corporations, the Scottish Committee of the British Medical Association, and of one representative from each of the areas in Scotland, numbering between 56 and 60. A small committee was appointed to take the necessary steps to summon this body to meet as early as possible. The representative from the areas is to be selected by postal voting papers. When this council or conference meets it will have to decide what line or lines of policy the profession is to adopt in connexion with the Insurance Act. It is felt that such a council, with the executive that will have to be formed from it, will give steadiness to the profession in Scotland, will command public confidence, and will make the community realise how very seriously the Act threatens to disturb, not only medical practice, but medical education and all the higher things that modern medicine stands for. What steps and what policy may be ultimately determined upon it is impossible to say, but meanwhile there is time given for a calm and clearer view of the position, and from this it is not to be doubted that a wise policy will ultimately emerge. It is no small credit to Scotland that the various interests and different views have been brought so far together.

Scottish Poor-law Medical Officers' Association.

In the committee's report for 1911, signed by Dr. Gilbert Campbell, Dr. Matthew Martin, and Mr. W. L. Muir, it is stated that during the year detailed information was supplied to a large number of applicants in regard to the following appointments,—viz: Barra, Aberdeen Poorhouse, Colonsay, Gesto Hospital, Skye, Burra Isles, Resolis, Rosemarkie, Lunasting, Nesting, Tiree, Ochiltree, Dunnet, Olrig, Glenlivet, Coll, Far, and Arrochar. The outgoing medical officers willingly supplied the necessary details in every case, so that each applicant knew with accuracy the nature of the

appointment. Many members asked for advice in their difficulties. On behalf of a member a question put to the Local Government Board elicited the reply that no complete set of rules for the guidance of medical officers is in existence, but the Board have in view the issue of a book of rules and regulations relating, *inter alia*, to the duties of Poor-law medical officers. In reply to many queries, members were apprised that medical officers must attend pensioners as private patients, unless in cases where the parish council grants a medical relief order, then the medical officer must attend the case as part of his duties without any extra remuneration from his parish council. If the medical officer's salary is inclusive of medicine he must supply the medicines as to ordinary paupers. But if his salary is exclusive of medicines he will charge the cost and recover it from his parish council. A communication received from the Local Government Board states that questions are arising in connexion with the granting of medical relief to old-age pensioners, as to which no general instructions have yet been issued. A member asking if he was entitled to a fee for attending a pauper confinement in a case belonging to an outside parish was advised that this would wholly depend on whether midwifery cases were specially excluded in his agreement with his parish council, but it was believed that a parish council in such cases could legally pay a fee. Several cases of dismissal of non-resident medical officers have occurred. The advice given was that no medical officer has any tenure of office, but can be dismissed by the parish council without stating cause, that the length of notice must be reasonable, and depends on how the salary is paid—monthly or quarterly. Where another medical man starts practice in the district of a non-resident medical officer in the interests of the public the new man should hold the appointment. Several cases of dismissal of medical officers without cause being given have occurred, and the committee have been asked to use their influence on behalf of the dismissed medical officers, but the committee, after considering the statements of the medical officers, as well as information from independent sources, concluded that in no case would their interference be justified. A large correspondence has taken place in connexion with the Insurance Act. No definite advice could be given, as everything would depend on what terms, if any, could be arranged with the Insurance Commissioners concerning amount of remuneration, wage limit, mileage in country districts, and supplying of drugs. Combination of the profession is essential. No movement has been made regarding Parliamentary action; in the present state of affairs it is utterly hopeless. An association has been formed to get Poor-law officials—inspectors, governors of poorhouses, medical officers, clerks—brought under a scheme of superannuation. The annual general meeting will be held in the St. Enoch Hotel on Jan. 26th, at 4.30 P.M., to adopt the report and elect office-bearers for the coming year. All Poor-law medical officers are urged to join the association. The financial report was good. The secretary is Mr. W. L. Muir, 1, Seton-terrace, Glasgow.

Lead-glaze Dangers.

An important prosecution under the Factory Act was heard in Paisley Sheriff Court last week. His Majesty's inspector under the Factory Act prosecuted, and stated that the firm, who were fireclay manufacturers, had employed a woman in the process of ware cleaning without having arrangements made for the scrapings to fall into water. In this case they had been allowed to collect on a piece of brown paper. Samples of the scrapings were analysed, and one contained 60·7 per cent. of lead monoxide and the other over 40 per cent. Against the same firm another instance was cited where a woman was found engaged in the process of painting majolica glaze without being provided with suitable overalls. In each case the sheriff imposed a fine of £5.

Aberdeen and Consumption.

It has been decided to erect at the City Hospital, Aberdeen, a second open-air shelter, capable of accommodating seven people, and costing, with the necessary bath-room accommodation, about £100. The existing shelter accommodates 15 patients and is at present used for males. The fact that there are 20 applications from females has made it necessary to erect this extra shelter.

Wick Medical Officers' Salaries.

At a meeting of the Wick parish council held on Jan. 15th it was decided, by a narrow majority, to increase the salary of Mr. C. G. Rae, recently appointed medical officer for the southern division of the parish, from £40 to £60, to equalise it with the salary of the medical officer of the northern division of the parish. The salary was originally fixed at £40 on the understanding that the other medical officer's salary was to be reduced to the same figure. This arrangement, however, the Local Government Board has refused to sanction.

Jan. 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Act and the Poor-law.

A CURIOUS point has arisen in Belfast bearing on the sanatorium benefit. According to the Act a million a year is set aside for sanatorium benefit, while a special grant of 1½ millions is to be given to local authorities—e.g., county councils—for building or for making grants to sanatoriums, but those in receipt of Poor-law relief are excluded from all these benefits. Now, in Belfast the board of guardians have built and equipped at a cost of £40,000 a magnificent sanatorium with 265 beds—by far the largest and finest one in Ireland; yet because a board of guardians built it they cannot be recouped for outlay upon it, while other public bodies will be recouped for outlay on much smaller institutions. Three-fourths of the patients in the Abbey Sanatorium will be of the insured class. In Belfast the city corporation have made pulmonary tuberculosis a notifiable disease, and yet in the Forster Green Hospital, which has 70 to 75 beds, the public health committee have only 20 to 30 beds retained for consumptives. How, therefore, are the insured patients with pulmonary tuberculosis to be dealt with in Belfast? The corporation have not sufficient beds, and under the Act the Abbey Sanatorium with its 265 beds cannot be used. The only solution will be for the city corporation, which is a county council, to take over the institution. Having made the disease notifiable, they will have to provide means to treat it.

Prevention of Infant Mortality in Dublin.

The first annual meeting of the Dublin Committee for the Prevention of Infant Mortality was held last week under the presidency of the Lord Mayor. The work of the committee is carried out by a number of ladies who visit in the poorer parts of the city and give advice to the mothers of young children. They have been especially trained in their duties, and at present some 80 of them are at work. In the six months during which the committee has been active about 2000 visits have been paid.

Medical Inspection of Schools.

Last week Dr. Oliver Gogarty, surgeon to the Meath Hospital, Dublin, gave a public lecture advocating the medical inspection of schools in Ireland. He pointed out that the money of the State was now spent in attending to the effects of disease and not the cause. There was good reason why the Commissioners of National Education should call upon the Treasury to support the Irish schools more thoroughly than they did at present, because Scotland, which had the same population as Ireland, got double the educational grant that Ireland got. The cost of one policeman in Ireland was as much as the cost of the education of 49 children.

Bicentenary Celebrations of the School of Physic, Trinity College.

A meeting of medical graduates of Dublin University was held in the Anatomy Theatre, Trinity College, on Jan. 22nd, under the presidency of Mr. R. H. Woods, President of the Royal College of Surgeons, to consider what part the graduates will take in the bicentenary festival next July. As at present arranged the festival programme will be as follows:—On Thursday, July 4th: Reception of guests and delegates in the College Library at 3.30 P.M. In the evening: Dinner in the dining-hall, followed by a dramatic performance in the Examination Hall by members of the University Amateur Dramatic Society. On July 5th: A commemoration service in the College Chapel followed by unveiling of memorial stone to Dr. Stearne by the Provost and an address by the Rev. J. P. Mahaffy. At noon

presentation of addresses by delegates. In the afternoon a garden party and in the evening the graduates' dinner. On July 6th: Visit to medical school, followed by reception at the Royal College of Physicians. Conferring of honorary degrees at 1 P.M., followed by a garden party. The honorary secretaries of the festival committee are Dr. W. G. Harvey, Mr. S. S. Pringle, and Dr. R. J. Rowlette. It is under discussion that the graduates should present the school with some permanent memorial of their affection.

Fire-guards and Injury to Children.

A case was heard in Kingstown police court the other day in which a woman was prosecuted by the police for leaving her children in a room with a fire and without a fire-guard. The incident had occurred on Dec. 22nd, and one of her children had been fatally burned. Evidence was given by the inspector of the Society for the Prevention of Cruelty to Children that he had warned the prisoner as to the risks she ran in neglecting to provide a guard. The magistrate contented himself with inflicting a fine of 10*s.*, presumably because this was one of the first prosecutions, if not the first, in Dublin for such an offence.

The Women's National Health Association and the Insurance Act.

The movement for organising a "National Health Insurance Society," which I referred to last week, has occasioned a division of opinion in the Women's National Health Association. The Insurance Act is not popular in Ireland with almost any party. The dropping of medical benefits has irritated a great many of the working classes for whom the Act was mainly drawn up—that is, especially those engaged in industries. Why should a worker in England and Scotland have medical benefits and be debarred them in Ireland unless he has been previously registered in those countries? And if, being previously registered in England and Scotland, he comes over to Ireland and claims medical benefits, this very fact puts Irish workmen in an inferior position. Finally, since the medical profession regards the Insurance Act as interfering with its interests, as injuring the hospitals, as sanctioning the very worst type of practice, and as tending to lower the whole scientific status of medicine, it cannot well support a movement to found a society under such an Act until its provisions affecting medical men are adjusted to what they regard as fair. While the Insurance Act is now the law of the land, its proper administration depends really upon the medical profession. The medical profession are quite prepared in Ireland as in other parts of the three kingdoms to work this Insurance Act, but they ask in fairness that their position should not be injured by it, and until it is completely altered they fear that this is what will happen. Ireland is at present being covered with officials, some to explain the Act, others to carry out its provisions, with the natural result that voluntary workers feel that there is no longer need or room for them.

The Shannon Floods.

For several weeks past the floods along the banks of the Shannon have been rising so high that now thousands of acres on both sides of the river are under water. Large districts of the counties of Roscommon, Galway, and Tipperary, and of King's County, have been deserted by their inhabitants. In other places all transit is by boat, and many houses are still occupied which are invaded by water to the depth of a foot or two. A midwife had an extraordinary experience the other day near Derryholmes, in King's County. She was called to attend a patient, and had to drive through a flooded road for a distance of two miles with the water up to the axle of her trap. On getting to the house she found the floor of the bedroom covered with water to the depth of 8 inches, and the posts of the bed upon which the patient lay resting on bricks to keep the bedclothes out of the water. Two buckets were inverted and a plank laid across them to enable the nurse to attend her patient.

Typhus Fever in Listowel.

A severe epidemic of typhus fever has broken out in the town of Listowel in the northern part of county Kerry. So grave is the situation that the quarter sessions, which should have been held last week, were postponed without the transaction of any business. Sir Acheson MacCullagh, Local Government Inspector, visited the town last week and found the streets and lanes in a shockingly filthy condition. In many of them heaps of manure had been allowed to accumulate for months. No attempt had been made to disinfect the houses where deaths had occurred, and in one house people were found sleeping in the bed in which a patient had died of typhus fever a few days earlier. Dr. J. T. Dillon, medical officer of health of Listowel, has frequently warned the urban sanitary authority of the dangers likely to arise from their neglect, but without effect.

Jan. 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Prosecution of Physicians.

DURING the summer an epidemic of cholera causing considerable alarm occurred in many countries. In August two cases of cholera were found at Fougères and at Saint-Suliac, two little seaports near Dinard and St. Malo. The news spread quickly, and to prevent an exodus of bathers the municipal authorities declared that the rumour was absolutely unfounded. Some days later, however, an epidemic of choleriform enteritis ravaged Saint-Suliac and its vicinity, lasting two months, at the end of which period the administration of the Prefecture opened an inquiry to fix the responsibility. It was found that the *prélèvements* on the bodies had not been made at Fougères, and that at Saint-Suliac the legal notification, which would have occasioned the speedy intervention of the health department, was not made until long after the appearance of the disease. On the report of Dr. Le Normand, the medical inspector of epidemics, four medical men have been brought before the Procureur-Général by the administration of the Prefecture. Their defence is that they delayed making a return because the cases appeared doubtful, and as they were not sure of their diagnosis they preferred to wait.

Disturbances at Angers.

The medical students of Angers have been indulging in violent displays because, at the request of the executive committee of the Union of French Women, a series of conferences on puericulture had been announced to take place and the first address was made one evening by Dr. Legludic. An audience of 200 women was assembled before the school when 100 students attempted to prevent their entrance. Their efforts being frustrated by the director of the school the students next tried to break up the conference by shouts and deafening yells. At the close of the meeting the audience found the egress obstructed. This demonstration was due neither to political reasons nor to personal animosity against Dr. Legludic, but because they complained that in consequence of a smattering of medical knowledge the women criticised the proceedings of the masters of science.

The Life of Tissues Outside of the Organism.

Professor Carrel, of New York, pursuing his researches on the power of tissues to live and develop outside the organism, has undertaken a new series of experiments, the results of which were reported on Jan. 17th to the Academy of Medicine by M. Pozzi. On placing fragments of living tissues in appropriate organic media Professor Carrel shows that these tissues retain their individual life, their cells living and multiplying, thus increasing the volume of the fragment experimented with. This result hitherto has been maintained only for a brief period, from 2 to 15 days. But in his last experiments Professor Carrel has succeeded in causing fragments of tissue to live and grow for nearly two months, by alternating periods of culture in animal plasma in the incubator with periods of latent life in Ringer's liquid maintained at 1° C. Only the invasion of the culture by microbes seems to have prevented the prolongation of the experiments. We may yet see the day when, all technical difficulties having been surmounted, for instance, a regular circulation of nutritive plasma around living fragments with elimination of their waste products having been secured, the artificial conservation of real life in organs detached from the body—a veritable miracle of physiology—will be realised.

Closing of the Paris Faculty of Medicine.

On various occasions I have referred to the disturbances at the Paris Faculty of Medicine during the past three years and

periodically at the course of M. Nicolas. After the last outbreak the courses were suspended until Jan. 6th. It was hoped that this lesson would suffice for the students and discourage them from further manifestations. The new Minister of Public Instruction, M. Guist'hau, falling back on a measure threatened but not made use of by his predecessor, posted a final notice on Jan. 17th, stating that if order was not maintained at the lecture of Jan. 18th the Faculty of Medicine would be closed to students of the first and second years up to the end of the first semester of the scholastic year. Most of the students had resolved to refrain from further annoyance of M. Nicolas. A notice was posted on the doors of the Faculty that only students of the first and second years would be admitted to the great amphitheatre. No disorder followed, but at 4 P.M. on the day of the course some students left the practical school to gather before the gate of the Faculty and read the notice. Some policemen thought it necessary to interfere and order the gates of the Faculty, which were ajar, to be opened. A hundred young men released from all control rushed into the great amphitheatre, climbed upon the stairs, and began a tumult. M. Nicolas endeavouring to withstand the storm remained a few moments in the well, but the noise continuing he left the place. The rioters thus left in possession called for the dean, M. Landouzy, who responded to their call and pointed out to them that by acting in this fashion they would cause their fellow-students to lose a year of their curriculum and perhaps spoil their career. The students leaving the amphitheatre scattered themselves through the streets, provoking considerable excitement in the Latin Quarter. The students of the first and second years held a meeting of the corporate society at the hotel, and after a lively discussion elected a committee of six, who were deputed to inform the Minister that the "troubles could not be imputed to them, as by the negligence of the dean no control had been exercised at the entrance."

The Rise of the Seine.

Happily the fears recently prevailing of a fresh rise of the Seine have been dispersed, for the river has begun to fall. It is hoped that the fall will continue.

Jan. 22nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Investigations on the Effect of Internal Treatment in Cases of Malignant Growth.[1]

Professor von Wassermann recently read before the Berlin Medical Society a paper on the use of internal remedies in the treatment of malignant growths in animals. He said that certain very resistant growths in mice were by Professor Ehrlich and others classified as cancer and sarcoma. These growths never disappeared spontaneously, but were composed of most resistant tissue. Remedies directly applied to the growth were useless for therapeutic purposes, because it was obviously impossible to know how wide the growth had already spread. He therefore tried to find a compound which after being injected into a vein would automatically leave the circulation and act directly on the cells of the tumour. By certain experiments he had found that the local administration of selenium and tellurium destroyed the cells of the growth, but intravenous injection of telluride and selenide of sodium in mice had no effect on the growth, the cause being that the compound administered in this way did not reach the tumour. Moreover, the highly poisonous action of the preparations allowed the injection of only very small quantities of them.

Professor von Wassermann said he had tried to produce chemical compounds which would convey the selenium and tellurium from the blood to the growth. This could only be done by substances easily diffusible in the living organism, such as are certain compounds belonging to the fluorescin series, including eosin and others. He succeeded in producing a compound consisting of selenium and eosin, which for the full development of its effect had to undergo a very complicated chemical process. When this substance was injected into the caudal vein of a healthy mouse there was a well-marked reddening of the entire animal, beginning even before the completion of the injection, and by degrees becoming stronger, especially on the mouth, the eyes, and the claws. In mice suffering from tumours no effect became visible after the first two injections made on two successive days, but after the third injection there was a softening of the growth, which after the fourth injection became still more distinct, presenting the appearance of a fluctuating cyst. The liquefied substance was then absorbed; the sac became smaller and the capsule smoother, so that only a long œdematous cord remained. After the fifth and sixth injections the absorption was really complete, and within ten days the animals had recovered. The effect was not, however, always such a good one. In the case of very large growths the animals became seriously ill simultaneously with the liquefaction of the growth and eventually died—a result which was probably due to a toxic influence exerted by the liquefied substance of the growth. A relapse had never occurred, but when for one reason or another the necessary number of injections could not be given so that cells of the growth were left undestroyed a relapse usually happened very quickly. On post-mortem examination it was found after the first injection that the growth was intensely reddened as compared with its unstained or only slightly stained surroundings. This fact showed clearly that the compound has a predilection for the tumour; this latter was found to be disintegrated and to consist of crumbly masses. In the second stage, where the healing had made further progress, the tumour was replaced by a lardaceous detritus in no way resembling the former growth. The effect of the compound was the same whether artificially produced or spontaneously grown tumours were used for the experiment.

Professor von Wassermann concluded that by an intravenous injection of a preparation of selenium and eosin he had succeeded in producing in mice the liquefaction and absorption of malignant growth, and when the tumours were not too large the animals recovered completely without relapses. He was careful to mention that he had not hitherto had any evidence to the effect that the compound would act similarly on the human species, although this might be shown by further clinical experiments. He also said that on microscopical examination he had found that the compound directly destroyed the nucleus of the cells of the growths, so that the growth itself was transformed into a detritus which was absorbed by the spleen and in a lesser degree by the liver. No damage was done to the other tissues of the body.

The experiments of Professor von Wassermann and the results obtained by him are obviously of the greatest importance, because it has now for the first time become possible to act through the circulation exclusively on the tissue of the growth without attacking the normal tissues of the organism. There is, however, some doubt as to the exact relationship existing between the growths which occur in mice and the malignant growths in the human subject, and their identity has been expressly denied by Professor von Hansemann.

Termination of the Epidemic of Poisoning.

The mysterious epidemic of poisoning among the inmates of the municipal shelter in Berlin, after having continued for about a week, came to an end on Jan. 2nd, the number of persons attacked being 171 with 78 deaths. Great uncertainty at first prevailed as to the nature and cause of the disease, but in the summary of the events of the first five days of the outbreak, which appeared in THE LANCET of Jan. 6th, I mentioned that by Dec. 31st it was suspected that the mischief might be due to the consumption of cognac adulterated with methyl alcohol. Chemical examination was undertaken of the cognac supplied in certain public houses in the neighbourhood of the shelter to ascertain if this suggestion was correct, and when these establishments were closed by the police the epidemic at once ceased. The wholesale dealer from whom the adulterated cognac had been procured was also discovered, and in his cellars the police found great quantities of methyl alcohol, a portion of which he had sold as genuine ethyl alcohol. He was arrested and will be prosecuted for manslaughter through negligence.

In the course of a discussion on the epidemic held at a recent meeting of the Medical Society Professor Stadelmann, chief physician to the Friedrichshain Hospital, described the symptoms of the disease, the characteristic points being, in severe cases, sudden colics, vomiting, cyanosis, and paralysis of the respiratory muscles,

[1] See THE LANCET, Jan. 13th, 1912, p. 112.

the heart, however, continuing to beat for some time later. Death in severe cases occurred within a few hours. On the other hand, some patients whose first symptoms were comparatively mild became dangerously ill at a later stage. Amaurosis was frequently observed. According to a statement of Professor Pick, prosector of the Friedrichshain Hospital, the microscopical examination of the retina showed certain alterations of its cells, so that the sight failed. In some cases the optic nerve showed also certain alterations.

During the discussion attention was drawn to several anomalous features observed in the attacks. Some patients, for instance, had died after taking only a small quantity of the deleterious cognac; whereas others had drunk large quantities of it without developing any symptoms of illness. It was also ascertained that only inmates of the shelter were attacked, although the public-houses in question had other customers besides them. Some medical men consider that pure methyl alcohol is not so poisonous as has been stated, and that a combination of methyl alcohol with other unknown substances must therefore have been the cause of the epidemic. The important fact, however, is that the poisoning came to an end at once on the closing of the places where the adulterated cognac was retailed.

Jan. 15th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Retirement of Professor Ludwig.

Professor Ernst Ludwig, the lecturer on chemistry of the Vienna Medical Faculty, has just completed his seventieth year, which, according to our university statutes, is the age-limit for active service upon the teaching staff. In exceptional cases an extension of a year, the so-called Ehrenjahr, or honorary year, is granted, the result being that the teacher in question retires from the university when he is 71 years of age. Professor Ludwig is a favourite with the students in Vienna. He has for many years been teaching medical chemistry, and former pupils of his at present occupy nearly all the chairs of chemistry in the Austrian universities. He is one of the principal members of the Austrian Board of Health, and to his initiative we owe numerous improvements that have been made in the existing regulations as regards public health administration; forensic medicine also owes to him a great deal of its modern development. A number of former pupils and friends of the professor have already offered him their congratulations on the occasion of his birthday, whilst the official celebration will take place some time later.

Suicides and Alpine Accidents in 1911.

The official statistics show that during the 17 years from 1893 to 1910 there was a constant annual increase in the number of persons taking their own lives, the figures rising from 380 in the year 1893 to 640 in 1910, but there is now some consolation in finding that 1911, the year just closed, was in this respect no worse than its immediate predecessor. The number of suicides in 1911 was, in fact, 640, the same as in 1910, only with the difference that the range of age has widened. There were 6 instances of suicides among children, an increase as compared with any previous year, the youngest being a boy of 9 years, whilst at the other end of the scale the oldest person had passed 82 years of age. As regards the age distribution, the majority were between 25 and 50 years, and 75 per cent. were males. As the motive for self-destruction, bad health was assigned in 28 per cent., misfortune in 37 per cent., disappointment in love in 12 per cent., fear of punishment in the case of the 6 children already mentioned and 7 adults (2 per cent.), whilst other reasons not clearly known were responsible for the remainder. With respect to the means employed, shooting was preferred by men and drowning by women, whilst hanging and poison were resorted to in an equal percentage of the cases if sex is considered. Another interesting fact is the prevalence of suicides in the spring and summer months, May heading the list with 73 cases, June following with 64, and August with 63, whilst December and October show the lowest figures, 43 and 50 respectively. It might have been expected that the influence of the weather would cause just the opposite result. The number of fatal accidents to tourists in the Alps also shows a constant increase during the summer months, as is only natural. In 1911 about 130 persons lost their lives in accidents in the Austrian, German, and Swiss Alps; from October till February only 18 such casualties happened, whilst in July, August, and September 70 were recorded.

Restrictions on the Use of Methyl Alcohol.

Owing to the serious loss of life in Berlin caused by the drinking of methyl alcohol the sale of this substance has again been made the object of a special ordinance by the Austrian Board of Health. The employment of even the smallest quantity of methyl alcohol for the preparation of foods, drugs, sweets, or beverages, and in short for any purpose except for a strictly and purely industrial one, is now prohibited; the ordinance also specifies the purposes for which it may be used, such as the manufacture of varnish, polishes, and colours. Sporadic cases of poisoning by this alcohol occurred in Austria some time ago, but the cause of the symptoms was at once recognised and preventive measures were taken.

Salvarsan.

In order to arrive at a definite opinion as to the advisability or otherwise of injections of Professor Ehrlich's salvarsan a circular has been sent out to nearly all the medical men in this country inviting them to give the results of their experience of subcutaneous or intravenous injections of the remedy in question. This collective investigation has no official character, being conducted by a private practitioner interested in the subject. In this country there is a strong feeling against the indiscriminate use of salvarsan. One of our leading dermatologists, Professor Finger, has seen several cases which have made him distrustful of it, and have led him to believe that one of its components is especially dangerous to the auditory nerve. Professor Finger's observations have been corroborated by Dr. Alexander, and the result of this investigation is therefore awaited with general interest.

Jan 22nd.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Retrospect of the General Health during 1911.

THE health of foreigners in China during the past year has been better than has as yet been recorded. This is due to the progress of medical science mainly in the matter of sanitation, which is receiving increased attention from the medical officers of the different treaty ports who look after the "concessions" in them. Typhoid fever is being guarded against more strictly by warning notices containing information as to the causes of infection, &c., and malarial fevers are becoming less of a menace by improved drainage of the areas in which the foreign quarters are. One may say, speaking generally, that life in China nowadays has less risk, as regards the preservation of health among Europeans, than in any other country east of Suez, except Japan, if ordinary care be taken. In the Yangtze Valley cases have occurred in several Europeans of infection with schistosomum japonicum. This disease, only discovered in 1904, has become a widespread trouble in the Yangtze Valley, and in some of the rice-growing districts there as many as 50 per cent. of the riverine and lakeside male population suffer from it. So far it has only been observed among the fishermen and rice-farmers, and not at all among the women, who are small-footed and do not wade. In passing, one may add that the practice of foot-binding still remains universal among Chinese women. In the European cases symptomatic treatment, such as aperients, antifebrile medicines, and tonics, generally results in ultimate cure if the patients abstain from incurring further infection by wading in infested waters. But among the natives, who become reinfected many times through their constant occupation in the paddy fields or fishing bare-legged in the rivers and lakes, it is a deadly disease, generally resulting in death in from one to three years, often less. The chief symptoms are continued remittent fever with dysentery and progressive abdominal distension with very marked liver and splenic enlargement. The last stages are marked by ascites and general anasarca. Schistosomiasis is due to a small trematode worm about 11 mm. in length and 5 mm. in breadth. Every

conclusion so far points to the route of infection being through the skin of the feet and ankles. This parasite is being closely studied in several of the Yangtze river ports and well merits investigation. The lessons with regard to rapid spread which have been learnt from trypanosomiasis emphasise the importance of gaining a knowledge as to the extra-corporeal host, the haunts, embryonic development, and mode of spread of this trematode, all of which are as yet undiscovered.

Sickness and mortality rates unfortunately maintain their high level among Chinese. On all hands there is evidence of the increase of tuberculosis. I have frequently referred to this scourge, which is spreading throughout the Empire unhampered by any attempt to check it. Sanatoriums are unknown; not even the most elementary principles to limit infection, now so well established in Europe, are observed. To the student of public health tuberculosis in all its forms seems as hopeless a problem as the country's politics. Cholera and bubonic plague have touched China lightly this year. The former has been almost absent. Probably more accurate methods of diagnosis have resulted in a clearer definition between choleraic diarrhœa and the more virulent cholera Asiatica. Bubonic plague appeared in Canton (200 deaths per diem for a couple of weeks), Amoy, Pakhoi, Shanghai (one or two sporadic cases), and Foochow, but there is no evidence of its having occurred in any inland ports or in the Yangtze Valley. As pointed out in previous notes, typhus and relapsing fever have accounted for the deaths of many thousands of the famine-stricken class, who live huddled together under the most insanitary circumstances. In this land with 500 medical and over 2000 lay missionaries belonging to every imaginable sect there is abundant room and opportunity for those who are willing to practise and preach the Gospel of Public Hygiene. There are not, as in India, innumerable caste or religious restrictions, and, moreover, the average Chinese is a reasonable creature, and willing to listen if he is shown the right way. The incidence of small-pox, for instance, is gradually diminishing because of the willingness to accept vaccination, and, as the pneumonic plague epidemic showed, the officials and people were not averse to the carrying out of rigorous disinfection measures as advised by foreign medical men. What a field there is here for the prosecution of an active anti-tuberculosis campaign, especially at present, when new ideas are being taken up so generally! One would fain see a full half of the £100,000 which is being raised in England and America for a university at Hankow being devoted to medical education and the physical well-being of the people. £50,000 would suffice for the introduction and prosecution of a health campaign that would have a far-reaching effect. In the past few years Western medicine has established itself among the people and has met with a more ready response than has been the case with any other profession or foreign method of doing things.

Red Cross Work in the Rebellion.

Since my last letter the Imperial Government has accepted in its entirety the rules of the 1904 Geneva Convention, and Red Cross work is now being carried out in the field of conflict. The Central Government organised, under a high official, a society which received the recognition of the foreign ministers in Peking as the Red Cross Society of China. The practical work of this society was placed under the superintendence of Dr. J. G. Gibb, of the Peking Union Medical College, and three days later the hospitals in Peking were organised by him as base hospitals with their respective medical staffs, and ambulance and bearer parties were allotted to each. The curriculum of the college had to be interrupted, as three field companies were formed from among its graduates and students, with eight foreign doctors of the teaching staff as officers. Each division was sent out equipped with all that is essential for first aid, dressing station, and field hospital work. Of these three companies one has been to Hankow, and is now being moved to Honanfu in response to a request from General Chiang, who commands the Imperialist forces there. Another is working at Wuchang. The third company has been in the fighting between Government and Revolutionary troops in Shansi and has now moved down with them to Taiyuanfu. Branch societies have been formed in many of the northern cities and preparations have been made for the opening of base hospitals in case of need. In all cases the Chinese officials and foreigners, medical and lay, are working hand in hand. It is gratifying that at this important step in the progress of modern medical science in China the Central Government has, with the assistance of the foreign ministers, adopted so correct an attitude. And it must be hoped that this correctness will hold the field rather than the tendency of the Wuchang Revolutionary authorities to refuse strict adherence to the terms of the Geneva Convention.

Peking, Dec. 26th, 1911.

Obituary.

CECIL YATES BISS, M.A., M.D. CANTAB., F.R.C.P. LOND., M.R.C.S. ENG.

THE death of Dr. Cecil Yates Biss took place on Jan. 20th at his house in Melina-place, St. John's Wood, after many years of illness. Dr. Biss was educated at Downing College, Cambridge, where he was a foundation scholar, and at St. Bartholomew's Hospital. At the University he gained the University Winchester prize. He took a first class in the Natural Sciences Tripos, 1875, proceeding to the M.A. degree in 1879. In 1880 he took the M.R.C.S., and in the same year took his M.B. degree and became a Member of the Royal College of Physicians of London. He proceeded to the M.D. at Cambridge in 1884, and in 1889 was elected to the Fellowship of the Royal College of Physicians. He was at one time examiner in medicine and materia medica at the Apothecaries' Society of London, and in materia medica at the Royal College of Physicians of London. He was appointed physician to out-patients at the Middlesex Hospital and lecturer on pharmacology and therapeutics at the Medical College, and physician to the Brompton Hospital for Consumption, honorary physician to the Western General Dispensary, and assistant physician to the Metropolitan Free Hospital. He was also consulting physician to St. Saviour's Hospital and to Friedenheim (Home for the Dying), a consulting medical officer to the Colonial Mutual Life Assurance Society, and demonstrator of physiology to selected school teachers, South Kensington. Dr. Biss contributed various papers to medical periodical literature, chiefly in relation to diseases of the chest. His work bade fair to bring great credit on himself and his profession when he unfortunately suffered, about 12 years ago, a hemiplegic stroke, which left him permanently paralysed and brought a career of great promise to an untimely end.

CHARLES WARDEN, M.D. ABERD., F.R.C.S. EDIN., M.R.C.S. ENG., L.S.A.,

HONORARY CONSULTING SURGEON TO THE BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.

Dr. Charles Warden died at his residence, Southside House, Weston-super-Mare, on Jan. 13th, in his eighty-fifth year. Dr. Warden received his medical education at St. George's Hospital, London, and also studied at Paris. He took the M.R.C.S. Eng. in 1850, the L.S.A. in 1851, in which year also he graduated as M.D. at King's College, Aberdeen. He had at one time a large practice at Birmingham, and was closely identified with philanthropic work there. He was consulting surgeon to the Birmingham and Midland Ear and Throat Hospital and to the Midland Counties Royal Orthopædic and Special Hospital, as well as to the Birmingham Royal Deaf and Dumb Institution; he was also on the honorary staff of the Birmingham General Dispensary and the Lying-in Hospital. In 1888 he was elected president of the British Benevolent Society, and in 1891 he was vice-president of the Laryngological Society. In 1890 he was President of the Otological Section of the British Medical Association, and in 1891 vice president of the British Laryngological and Rhinological Association. He took a great interest in all municipal matters in Birmingham, and was a magistrate for the city. He went to Weston-super-Mare ten years ago, where he was highly esteemed and respected, and much sympathy is felt there for his widow and four children. The funeral took place at the local cemetery on Jan. 17th, the first portion of the service being at the parish church.

EUGENE STEPHEN YONGE, M.D. EDIN.

WE regret to announce the death of Dr. E. S. Yonge, which took place at his residence, Old Trafford, Manchester, on Jan. 12th. He had been a sufferer from some obscure affection for a number of years. Dr. Yonge took the degrees of M.B. and C.M. at Edinburgh University in 1891, and the M.D. in 1897. He subsequently did post-graduate work in Vienna, Berlin, and Paris, and was for a time house surgeon in the Southern Hospital for Women and Maternity Hospital, Manchester, before specialising on diseases of the throat and nose. His activity was displayed specially in the direction of rhinology. His treatment for asthma and hay fever by means of "resection of the nasal nerve" is said to have proved very successful, and has been the subject of keen discussion. Some short time ago Dr. Yonge resigned some of his appointments. He was a physician to the Crossley Sanatorium and the Manchester Hospital for Consumption and Diseases of the Throat. He published many papers on his specialty, and quite recently there appeared his "Handbook of Diseases of the Nose and Throat." This work took much of his time. He was a man of exceptional skill and noted for his kindness to his patients. Death was due to heart failure.

JOHN SHIVES, M.D. ABERD.

A well-known general practitioner in the Bradford district passed away on Jan. 5th, in his sixty-seventh year, at his residence, Arnage, Shipley, after an illness lasting many months.

Dr. Shives was a native of Ellon, Aberdeenshire, and was educated at the University of Aberdeen. He qualified as L.R.C.S. and L.M. Edin. in 1868, M.B., C.M. Aberd. 1869, and M.D. Aberd. in 1876. His chief professional work was done at Liversedge, where for many years he enjoyed a large general practice, during the conduct of which he was elected an honorary surgeon to the Dewsbury Infirmary. His services were greatly valued in the neighbourhood, both in public appointments and among private patients. On leaving for London in 1894 he was the recipient of valuable farewell presents from both patients and personal friends. When in London he became a barrister-at-law, and after travelling in the United States returned to Yorkshire and settled in Shipley. The interest he took in his profession was deep, and he kept it up to the last. Those who knew him intimately will long remember his geniality, shrewdness, and kindliness. Dr. Shives was buried among his own kith and kin at Allenvale Cemetery, Aberdeen.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Wilhelm Franz Loebisch, emeritus professor of medical chemistry in the University of Innsbruck, aged 72. In the earlier years of professional life, after having graduated in Vienna, he took medical charge of a ship and afterwards served as a volunteer surgeon with the German army in 1870. Having formerly been a pupil of Hoppe Seyler in Tübingen he was appointed assistant to Professor Maly of Innsbruck after the close of the Franco-German war, and in 1874 became assistant to Professor E. Ludwig in Vienna, whence he was induced to return to Innsbruck by the offer of an extraordinary professorship of medical chemistry in 1878. Some four years later he was promoted to be ordinary professor, retaining the chair until he reached the regulation age for retirement—70. He published a well-known work on Urinary Analysis and edited a magazine which was the forerunner of the widely read *Therapie der Gegenwart*.—Dr. H. J. Billeter, extraordinary professor of odontology in the University of Zürich, aged 77.

DEPUTY MEDICAL OFFICER FOR LONDON.—At the suggestion of Dr. W. H. Hamer, the new medical officer of health for London, the London County Council has decided to appoint a deputy medical officer of health and deputy school medical officer, instead of filling the position of assistant public health medical officer left vacant on the promotion of Dr. Hamer to his present office. The salary will be £1000 a year. Members of the Council's medical staff will not be precluded from applying, and the age of the applicants must not exceed 50 years.

THE NATIONAL INSURANCE ACT.

THE GOVERNMENT AND THE INSURANCE ACT.

IT is announced that the Conference on the National Insurance Act at the London Opera House, Kingsway, which is to be addressed by the Chancellor of the Exchequer, will be held on Monday afternoon, Feb. 12th, and not on Feb. 5th, as previously stated. The Conference is being arranged jointly by the National Liberal Federation and the National Insurance Committee. The chairman of the latter body is the Master of Elibank, and the only medical member is Dr. Christopher Addison, M.P.

THE ABUSES OF CONTRACT PRACTICE.

A recent letter in the *Times* from Mr. James Milward, a retired practitioner, gives a lurid description of the kind of "cheap doctoring" which is, or at least was, possible under the worst forms of contract club practice. The writer, however, does not seem to recognise that the avowed intention of the Act is to render such occurrences impossible in the future, although it is open to doubt whether the methods proposed by those who framed the measure will succeed in so doing. Mr. Milward describes, in terms which may have been justified by things which have happened in the past, the degradation into which contract practice can fall. In so far as the National Insurance Act in its present form threatens to perpetuate the evils of contract practice, his words may be considered to constitute a timely warning; but it is fair to remember that clauses of the Act have been framed especially to produce a contrary result.

THE HOSPITALS AND THE ACT.

With reference to the probable effect of the Insurance Act on subscriptions to voluntary hospitals Mr. Sidney Holland has lately written to the press from a point of view which, we believe, differs from that previously expressed by him. He regrets the possible withdrawal of subscriptions to the voluntary hospitals, which it appears to him are following on the promulgation of the terms of the Act, while he agrees that the hospitals will have to admit a vast number of in-patients as at present. He foresees that if the public continue to withdraw their subscriptions the hospitals must close or else become rate- or State-supported, and urges the public to wait a little and see how things develop before refusing their help to the sick poor.

THE SCOTTISH CENTRAL COMMITTEE.

Our Edinburgh correspondent announces that the Central Scottish Council for the purpose of dealing with medical questions arising out of the Insurance Act is now almost an accomplished fact. It is expected that the Council will adequately represent all the medical interests in Scotland, including the Universities, the corporations, and the Scottish committee of the British Medical Association.

THE NATIONAL MEDICAL UNION.

A meeting of the executive committee of the National Medical Union is being held at Manchester to-day (Friday). The executive of the union has been at work since it came into existence soon after the mass meeting at Manchester on Dec. 14th, and a statement of its past and future action is expected shortly. The honorary secretary is Dr. T. Wheeler Hart, Avenham House, Stretford, Manchester.

THE BRITISH MEDICAL ASSOCIATION AND THE ACT.

The Council of the British Medical Association has declined to call an extraordinary general meeting of the Association in accordance with the requisition signed by 564 members and presented by Dr. F. J. Smith; but a special meeting of the Representative Body of the Association will be held towards the close of next month, probably on Feb. 21st. The next quarterly meeting of the Council will be held on Jan. 31st.

We understand that the Reform Committee of the British Medical Association, whose headquarters are 129, Old Queen-street, Westminster, is actively engaged in the formation of branches throughout London and the provinces. Fourteen provincial and seven metropolitan branches of the Reform Committee are in process of formation, and the executive is in touch with a similar committee which was formed at Birmingham as a result of the mass meeting held there in December. Meetings are being arranged throughout the suburbs and provinces.

Dr. Alfred Cox, acting medical secretary of the British Medical Association, in a letter addressed to the secretaries of the English and Welsh branches of the Association, dated Jan. 4th, draws attention "to the fact that the setting up of Local Medical Committees in no way commits the local profession to form panels of practitioners for the purposes of the Act." In the opinion of the Council such committees, on the contrary, "will be equally useful if when the regulations are drawn up it is found that they are such as to justify the profession in refusing to form a panel and in organising opposition." It is obviously important that local medical bodies should be able to organise local medical opinion and bring it to bear upon the Local Insurance Committees. The divisional areas of the British Medical Association, it is pointed out, do not correspond with the proposed insurance areas under the Act. The various branches are urged to considered the best means of using the machinery of the Association in these difficult circumstances.

A meeting of the Wandsworth Division of the British Medical Association was held on Jan. 22nd, and a resolution condemning the recent decision of the Council and approving of the formation of a Reform Committee was adopted with one dissentient. Mr. E. B. Turner, whilst insisting upon loyalty to the Association, said their object was to capture the machinery of the Association, and use it to deal in a more efficient way with the iniquitous Insurance Act. He advised the meeting to adopt a definite policy which would be put before the next Representative meeting by a representative whom they could trust not to be shaken or misled.—The Brighton Division has passed a resolution expressing the opinion that the Council, not having acted with due energy and firmness in their negotiations with the Government, should forthwith send an ultimatum informing the Government that they have advised every member of the Association to refuse service under the Act. Similar action has been reported from various other quarters.

THE ACTION OF MEDICAL MEN IN POPLAR.

At a meeting of the medical profession in Poplar on Jan. 17th the following resolution was carried unanimously:—

That a Union of the Registered Medical Practitioners practising in the metropolitan borough of Poplar be formed for the purposes of protecting the interests of the medical profession, securing united action in dealing with public bodies, and strengthening the bonds of professional fellowship in the borough, and that it be called the Poplar Medical Union.

A committee was elected to draw up rules.

It was pointed out that the Union was not in opposition to the British Medical Association, but was to look after the interests of the local profession. The majority of its members are also members of the British Medical Association. It is hoped by the Union that other boroughs will form similar unions.

SOCIALIST DOCTORS AND THE INSURANCE ACT.

AT a meeting of Socialist doctors held on Jan. 21st at 24, Upper Wimpole-street, London, the following resolutions were passed and ordered to be sent to the press for publication:—

That the only satisfactory method of treating existent disease and of safeguarding the public health is by the establishment of a properly organised State medical service, under which medical practitioners would become public officers employed and paid directly by the community for the purpose not merely of curing but of preventing disease.

That the medical arrangements proposed by the Insurance Act are in the main crude and unscientific, and as they stand will do little towards eliminating disease or reducing physical deterioration because the Act deals with effects rather than causes.

That the Act will perpetuate the worst features of many of the most unsatisfactory types of practice. But that having regard to the following facts: (1) That opinion in the medical profession and amongst the general public is not yet ripe for a nationalised and socialised medical service; (2) that the Act will bring an increasing number of doctors into the service of public authorities; (3) that the Act must inevitably lead to the public management and control of the voluntary hospitals. (4) that on the revision of the Act in 1915 women and children will almost certainly be included, and that there will then be an opportunity of enlarging its scope, and of remedying many of its present defects; this meeting of medical practitioners advises all Socialist doctors to accept service under the Insurance Commissioners, provided that the capitation system of payment is adopted as the ordinary method of remuneration, and that fair conditions of service are secured for the profession.

That the capitation system—i.e., a fixed payment to the medical attendant per head per annum—is the only system (short of whole-time salaried appointments) which harmonises the interests of the public, the patient, and the doctor.

That it is essential to conduct an educational campaign with a view of influencing public opinion and to ensure that when the Act is remodelled in 1915 every doctor shall become a public health officer whose duty shall be to search out and prevent disease instead of merely acting as a direct or indirect purveyor of physic.

Signed on behalf of the meeting,
C. A. PARKER, F.R.C.S.
ALFRED SALTER, M.D., J.P.
W. A. DAVIDSON, Hon. Sec.

235, Uxbridge-road, W., Jan. 22nd, 1912.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. St. C. Colson (Sections I. and II.), Westminster Hospital; J. F. O'Connell (Sections I and II.), St. Mary's Hospital; F. C. Shone (Sections I. and II.), University College Hospital; and W. H. Vincent (Sections I. and II.), St. Mary's Hospital.
Medicine.—H. St. C. Colson (Sections I. and II.), Westminster Hospital; E. B. Keen (Section I.), Charing Cross Hospital; J. F. O'Connell, (Sections I. and II.), St. Mary's Hospital; and C. B. Welsby (Section I.), London Hospital.
Forensic Medicine.—H. St. C. Colson, Westminster Hospital; R. J. M. E. Le Dentu, Bordeaux; J. F. O'Connell, St. Mary's Hospital; and H. Willis, Manchester.
Midwifery.—H. St. C. Colson, Westminster Hospital; M. P Dos Santos, Louvain; J. F. O'Connell, St. Mary's Hospital; C. G. Waddington, Leeds; and H. Willis, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—H. St. C. Colson, J. F. O'Connell, F. C. Shone, and W. H. Vincent.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Ernst Eltner has been appointed Lecturer on Odontology.—*Caracas:* Dr. F. Guevara Rojas has been appointed to the chair of Pathological Anatomy.—*Gratz:* Dr. M. Salzmann, of Vienna, has been appointed to the chair of Ophthalmology in succession to Dr. Dimmer.—*Groningen:* Dr. A. A. Hijmans van den Bergh, of Rotterdam, has been appointed to the chair of Clinical Medicine in succession to Dr. Wenckebach.—*Moscow:* Dr. A. Krinkoff has been recognised as *privat-docent* of Forensic Medicine.—*Prague (German University):* Dr. Hugo Pribram and Dr. Franz Bardachzi have been recognised as *privat-docenten* of Pathology.—*Würzburg:* Dr. Oskar Schultze has been promoted to the chair of Anatomy in succession to the late Dr. Ph. Stöhr. He is the son of a former professor of anatomy in Bonn and a nephew of the late Dr. K. A. S. Schultze, professor of anatomy in Greifswald.

UNIVERSITY OF LONDON: KING'S COLLEGE.—A course of four lectures will be delivered in the Physiological Laboratory, King's College, London, by Dr. Otto Rosenheim on the Bearing on Chemical Physiology of Certain Pathological Questions, at 4.30 P.M. on the following Mondays: Jan. 29th, Feb. 5th, 12th, and 19th. A discussion will be held on (1) the pathology of carbohydrate metabolism, including pentosuria; (2) the pathology of fat metabolism, including the rôle of cholesterin esters; (3) the anomalies of protein metabolism, including cystinuria, diaminuria, alkaptonuria, &c.; (4) the chemistry and the enzymes of tumours. These lectures are free to all members of King's College, London, to all internal students of the University of London, to all medical students in London, and to all medical men on presentation of their cards.

LITERARY INTELLIGENCE.—Mr. Murray's quarterly list of new publications contains several volumes likely to prove of special interest to medical men. Among them we find "The Poor-law Enigma," by Miss M. Fothergill Robinson, which contains an account and a criticism of the chief schemes for Poor-law administration now before the public; "The Genus Rosa," for those of botanical tastes, by Ellen Willmott, F.L.S., with drawings by Alfred Parsons, R.A., consisting of 128 coloured plates and 56 drawings in black and white; "Problems of Life and Reproduction," by Marcus Hartog, M.A., D.Sc; "The Anopheline Mosquito," by R. C. Dauglish; and a "Life of Paracelsus (Theophrastus von Hohenheim, 1493–1541)," by the late Miss Anna M. Stoddart.—Messrs. Constable and Co., Limited, are about to publish a work on "Post-mortems and Morbid Anatomy," by Mr. T. Shennan, F.R.C.S.Edin. The book is fully illustrated with photographs and colour plates. The same firm have also in the press a new work by Sir Almroth E. Wright, M.D., F.R.S., entitled "Handbook of

the Teat and Capillary Glass Tube and its Application in Medicine and Bacteriology." This volume is intended to provide for laboratory workers a training in technique, while being at the same time a critical text-book.

WE are informed that Dr. Marcus Sinclair Paterson, medical superintendent of the Brompton Hospital Sanatorium at Frimley, has been appointed medical director of the Welsh Memorial to King Edward VII.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting of this institution held on Jan. 18th the following list of office-bearers and members of council was adopted, viz.:—President: *Robert Jones. Vice-Presidents: W. B. Paterson, C. S. Sherrington, *C. J. Macalister, and *J. Lloyd Roberts. Treasurer: *R. J. Hamilton. General Secretary: Thomas Bushby. Secretary of ordinary meetings: *Alexander Stookes. Secretary of pathological meetings: *W. Blair Bell. Librarian: J. C. M. Given. Editor of the journal: John Hay. Council: Arthur Evans, R. E. Kelly, R. W. MacKenna, J. E. O'Sullivan, C. V. Vereker, O. T. Williams, *T. R. Bradshaw, *T. B. Grimsdale, *E. W. Hope, *W. S. Henderson, *N. P. Marsh, and *C. E. Solomon. Auditors: *O. T. Williams and *Henry Harvey. Those marked (*) did not hold the same office last year.

THE SMITH TURNER EXHIBITION IN DENTAL MECHANICS.—This scholarship, of the annual value of £30, was founded (1) to do honour to James Smith Turner's memory; and (2) to help those students who, in the opinion of the Fund Committee, have financial difficulty in completing the dental curriculum. The scholarship is open to any registered dental student who has not completed the curriculum required for a dental qualification. The scholarship will be awarded after examination, and be tenable for one or two years, at the discretion of the committee. The scholarship money will be paid to a dental school in Great Britain or Ireland approved by the committee in discharge of fees. The examination in dental mechanics will be both practical and *viva voce*. The next examination will be held during April, 1912, at a dental school and on a date to be announced later. Applications must be received on or before March 15th next, addressed to the Secretary, British Dental Association, 19, Hanover-square, London, W.

ASSOCIATION OF SCHOOL MEDICAL OFFICERS FOR SCOTLAND.—A meeting of this association was held at Perth on Jan. 20th under the chairmanship of Dr. E. T. Roberts, the President. A discussion on the Control of Infectious Disease in Schools was opened by Dr. A. A. McWhan, who detailed the scheme in operation in the county of Berwick; Dr. J. Hally Meikle outlined the procedure in the city of Edinburgh; and the discussion was continued by Dr. A. Gilmour, Dr. C. C. Finlator, Dr. G. E. Moffet, and Dr. G. Arbuckle Brown. The afternoon session was occupied by a discussion on the Work of the School Medical Officer. Dr. Gilmour, in opening the discussion, laid special emphasis on the work of the school medical officer in relation to the cleansing of children, the attendance of parents at inspections, and the instructions to teachers in regard to defective children. Dr. Roberts, Dr. Meikle, Dr. Arbuckle Brown, Dr. Finlator, Dr. Moffet, Dr. McWhan, and Dr. A. E. Kidd took part in the discussion, which showed the necessity for different methods of procedure in different districts, town or county, to meet the special requirements of each locally. The election of office-bearers will take place at the annual meeting of the association to be held in Glasgow on Saturday, March 30th next.

THE BALNEOLOGICAL CONGRESS, BERLIN.—The Thirty-third Congress of the Balneological Society will be held at Berlin from March 7th to 11th, 1912, in the lecture hall of the Polyclinic Institute of the University, Ziegelstrasse, 18/19, Portal V. Forty-five papers have been accepted for submission to the congress. The President will be Geh. Med.-Rat Professor Brieger. All communications with reference to the congress should be addressed to the general secretary, Dr. Brock, Berlin, N.W. 52, Thomasiusstrasse, 24. The prize of the Dr. Heinrich Brock Foundation of the Balneological Society for an essay on "Comparative Researches upon the Rapidity of Absorption of Mineral Waters and the Influence thereof upon Renal Function" is announced for competition. The prize amounts to 800 marks. Essays must be addressed before Nov. 1st, 1912, to Professor Dr. Brieger, Berlin N.24, Ziegelstrasse, 18/19. Each essay must be provided with a motto, and accompanied by a sealed envelope, bearing the motto and containing the name and address of the author.

MESSRS. M. MEZGER and Co., 63, High Holborn, London, W.C., have been appointed by the Jetter and Scheerer Company, surgical instrument manufacturers of Tuttlingen, to act as their sole agents for the United Kingdom and British colonies.

PRESENTATION TO A MEDICAL PRACTITIONER.—On Jan. 19th, Mr. S. F. Lusk, M.B., C.M. Edin., who for the past seven years has been in active practice in Ballymoney, was made the recipient of an address and presented with a purse of sovereigns by his friends in that district on the occasion of his leaving to begin work in his new appointment as dispensary medical officer of Loughbrickland, County Down.

UNITED KINGDOM POLICE SURGEONS' ASSOCIATION.—The annual meeting of this association was held on Jan. 17th, at which the report of the council was presented. The report expresses its high appreciation of the *esprit de corps* which is now being shown by the members of the association, in common with the general body of the profession, in strenuously endeavouring to protect the interests of the faculty and maintain that high standard of medical service which is essential for the proper discharge of its important duties for the State and the responsibilities which each one undertakes as police surgeon. The council go on to regret that there still exists in our medical schools a need for improvement in the teaching and study of legal medicine, and hopes that the State will make better provision for its skilled medico-legal experts by giving them every opportunity for obtaining material for their work, so that they may be stimulated to specialise and pay greater attention to the study of the subject. The proposed coöperation with other societies of analogous nature—viz., medical officers of health, metropolitan police surgeons, Poor-law, postal, factory, and school medical officers and public vaccinators—is being discussed by the Police Surgeons' Association, and on this matter the council desire early instruction.

THE THIRTEENTH SOUTH AFRICAN MEDICAL CONGRESS.—This Congress will be held at Johannesburg in Easter week, April 8th to 15th, under the presidency of Sir Kendal Franks, C.B., M.D., F.R.C.S. Irel. All medical practitioners registered in South Africa are eligible for membership and such other persons as the local organising committee may approve. The subscription is a guinea. From about April 1st all South African railways will issue return tickets at single fares. Members are invited to contribute papers to sections in which they are interested, but the papers must be submitted to the local organising committee a month before the meeting. The honorary general secretary is Dr. G. Ritchie Thomson, P.O. Box 908, Johannesburg. Six sections are planned—namely, Medicine: Secretary, Dr. E. P. Baumann, Johannesburg. Discussion will be opened (subject not yet announced) by Dr. A. B. Ward, of Bloemfontein. Surgery: Secretary, Dr. H. Temple Mursell, Johannesburg. Mr. H. A. Moffatt, F.R.C.S., of Capetown, will open a discussion on Hernia with Special Reference to the Workmen's Compensation Act. Obstetrics: Secretary, Dr. St. J. Stanwell, Johannesburg. Dr. D. H. Wessels, of Capetown, will open a discussion on Uterine Hæmorrhage. Public Health: Secretary, Dr. P. G. Stock, Johannesburg. Dr. L. G. Haydon, of Durban, will open a discussion on Malaria and its Prevention, with Special Reference to South Africa. Pathology: Secretary Dr. G. A. Turner, Johannesburg. Special subjects: Secretaries, Dr. A. R. Friel, Johannesburg; Dr. R. P. Mackenzie, Johannesburg; and Dr. F. H. Napier, Johannesburg. In the last two sections the subjects for discussion and the names of the openers have not been announced.

PERRY.—On Jan. 21st, at Fortfield-place, Sidmouth, Brigade-Surgeon George Perry, late Coldstream Guards, aged 78.

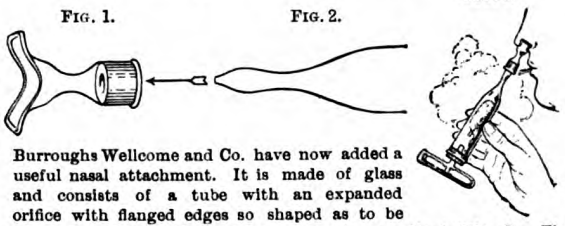
N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

NASAL ATTACHMENT FOR THE "VAPOROLE" AMMONIUM CHLORIDE INHALER.

IN THE LANCET of Jan. 15th, 1910, p. 182, we described an ammonium chloride inhaler introduced by Messrs. Burroughs Wellcome and Co. The inhaler consisted of a T-tube attached to a wide glass tube terminating in a mouth-piece, and it presented some advantages with regard to the blending and filtering of the vapours arising from the ammonia and acid contained in the T-tube. The apparatus, however, possessed no convenient means of using the inhaler for nasal inhalations. Messrs. Burroughs Wellcome and Co. have now added a useful nasal attachment. It is made of glass and consists of a tube with an expanded orifice with flanged edges so shaped as to be adapted to the physical configuration of any patient (Fig. 1). The attachment is fitted with a rubber plug having a hole to receive the mouth-piece of the inhaler (Fig. 2). Fig. 3 shows the inhaler applied to the nose. This form of nose-piece is perhaps to be preferred both on hygienic and æsthetic grounds to other forms which require to be inserted in the nares.

FIG. 1. FIG. 2. FIG. 3.



HOW MUCH ALCOHOL MAY BE FORMED LOCALLY IN THE STOMACH?

To the Editor of THE LANCET.

SIR,—I shall be obliged if any reader will inform me if any considerable percentage of alcohol, presumably due to local fermentation, is often found in the stomach. I am, Sir, yours faithfully,

IOTA.

A KEY TO NATURAL MINERAL WATERS.

WE have received from Messrs. Ingram and Royle, Limited, of 45, Belvedere-road, London, S.E., a copy of their pamphlet on "Natural Mineral Waters; their Properties and Uses." The compilation is most useful for reference, as not only are the details of analysis of the various natural waters set out, but short notes also are inserted as to the cases for which they are suitable. The appendix also contains a convenient summary of dietetic and therapeutic indications. The waters are classified into (1) aperient waters, (2) alkaline waters, (3) ferruginous or chalybeate waters, (4) sulphurous waters, (5) arsenical waters, (6) lithiated waters, (7) table waters, and (8) special waters.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th–14th (London).—Central Poor-Law Conference.
March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 9th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
" 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
" 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.

April 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
,, (London, Olympia).—Ideal Homes Exhibition.
Spring (London).—Second Optical Convention.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—J. H. Targett, W. W. H. Tate), at 11, Chandos-street, W., at 8 P.M.

Specimens:

Dr. Inglis Parsons: (1) Fibroid Tumour of the Uterus undergoing Degeneration; (2) Fibroid Uterus Removed 20 Years after Apostoli's Treatment.

Dr. Dauber: Suppurating Ovarian Cystoma, with Sarcomatous Degeneration of the Wall.

Dr. W. S. A. Griffith: (1) Assimilation Rachitic Pelvis; (2) Supravaginal Hysterectomy performed in Place of Induction of Abortion in a Case of Repeated Melancholia of Pregnancy.

Short Communication:

Dr. H. A. Colwell and Dr. Bryden Glendining: The Presence of Blood Pigment in the Fæces of the New Born.

Paper:

Dr. G. T. Western: The Treatment of Puerperal Septicæmia by Bacterial Vaccines.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson, Dan McKenzie), at 11, Chandos street, W.: at 4.30 P.M.

Cases

Will be shown by Mr. Herbert Tilley, Dr. W. H. Kelson, and others.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Mrs. Dickinson Berry, H. J. Scharlieb, C.M.G.): at 8.30 P.M.

Dr. P. S. Frew: The Significance of Acetonuria in Children.

Mrs. Dickinson Berry: Notes of a Case of Post-anæsthetic Poisoning; and Report on Experiments on Animals by Dr. A. L. Muskens made to Investigate the After-effects of Chloroform.

Mr. R. E. Apperley: Microscopical Specimens of Kidney and Liver from Cases of Post-chloroform Poisoning.

Discussion

On the Advisability of Rendering Official One or More of the Newer Local or Spinal Anæsthetics (introduced by the President).

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Cases.

HARVEIAN SOCIETY OF LONDON, Paddington Green Children's Hospital, W.

THURSDAY.—8.15 P.M., Cases will be shown by Members of the Hospital Staff. 9 P.M., Clinical Meeting.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Pathological Evening.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. MacCormac: Clinique (Skin). 5.15 P.M. Lecture:—Dr. W. Hill: The Difficulties and Dangers surrounding the Treatment of Chronic Laryngeal Stenosis. (Patients shown.)

TUESDAY.—4 P.M., Dr. G. Rankin: Clinique (Medical). 5.15 P.M., Lecture:—Mr. B. Robinson: Stones in the Gall-bladder, their Complications and Surgical Treatment.

WEDNESDAY.—4 P.M., Mr. J. Cunning: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. E. Clarke: Presbyopia and its Treatment.

THURSDAY.—4 P.M., Dr. L. Williams: Clinique (Medical). 5.15 P.M., Lecture:—Sir F. C. Wallis: Treatment of Joint Effusions and of Some Fractures.

FRIDAY.—4 P.M., Mr. R. E. Bickerton: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. G. Stewart: Clinical (Lecture II.).

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Morton: The Use of Carbon Dioxide Snow.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. E. Harman: Diseases of the Eye. 2.30 P.M.. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture II.)

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Symptoms and Treatment of Gall Stones.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 4.30 P.M., Lecture:—Mr. H. D. Gillies: Tumours of the Larynx. 5.30 P.M., Eye Operations (Mr. Brooks).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

NOTES OF

A Lecture

ON

MEDICO-LEGAL RELATIONSHIPS OF GENERAL PARALYSIS OF THE INSANE.

Delivered at the Medical Graduates' College and Polyclinic, Chenies-street, London, W.C., on Jan. 25th, 1912,

BY SIR GEORGE H. SAVAGE, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN FOR, AND LECTURER ON MENTAL DISEASES AT, GUY'S HOSPITAL; CONSULTING PHYSICIAN TO THE IDIOT ASYLUM, EARLSWOOD.

GENTLEMEN,—There is no doubt of the utility of bringing groups of conditions together and looking at them from a special standpoint, and I have to-day selected the medico-legal relationships of general paralysis of the insane.

INTRODUCTORY REMARKS.

General paralysis of the insane is one of the most interesting forms of brain disease associated with mental disorder. The disease is more or less definite in its course and in its fatal terminations, and it is pretty certain that syphilis is one of its most certain causes. Taking these facts into consideration, it is probably only a question of time before we discover some treatment which will arrest, if it does not cure it. If it is to be cured it must be detected early, and the medico-legal aspect brings one into relationship with many of the earlier cases and therefore is specially interesting.

General paralysis does not need here either a definition or a description, but I shall have to refer to several forms of the disorder and to different social dangers which may arise in these different forms or at different stages of the disease. First, there is the warning or prodromal stage, next there is the more acute stage, then the placid one which passes into the demented one. At each period there are particular dangers.

The greatest danger arises during the earlier stages, though in the weak-minded one there is risk of the patient becoming through his facility the tool of others. In the warning stage the chief characteristic is some loss of higher control so that the actions follow feeling rather than reason. They are often impulsive.

The result of defective control varies with the individual, and may either be represented by anger, violent language, and even brutal acts, by improper companionships and sexual faults of various kinds, or by marked acquisitiveness—the senseless taking of things for which there is no real want.

BRUTAL ASSAULTS.

First, then, a certain number of brutal assaults are made in the earlier stages of general paralysis of the insane. When we recognise the degrading tendency of the disease, with its inclination to seek for companions those belonging to a lower social order, it will be seen how the conditions leading to disorder of conduct are provided. Bad companions and drink, to which the general paralytic easily succumbs, may lead to violent personal attacks; and it is important to remember this, especially those of you who have anything to do with police cases, for I have known men who were general paralytics taken up for disorder of conduct, and when in the cells have been seen by medical men who have diagnosed drink from the alteration in speech which was really due to the disease, not to drink. In these cases there is no premeditation, and the attacks as a rule are impulsive and are not followed up. There is often regret at the actions and a wish to make amends.

SEXUAL RELATIONS AND OFFENCES.

General paralysis has always been looked upon as a disease in which the sexual functions play an important part. Formerly, sexual excess was considered the chief contributing cause, and now one recognises as an early symptom great development of desire, often with lack of power. In early general paralysis lust is almost always present, and may lead to what appears as a normal affection with offers of marriage. I regret to say I have seen such cases of marriage in haste and regret, on the wife's part, at leisure. The lust may be very great, and an insatiable longing which is very trying to the wife, or there may be, as in some cases with tabetic symptoms, desire which passes off very rapidly, leaving the man impotent. I have never had a case in which a plea for nullity of marriage under these conditions has been raised, but in several cases I should like it to have been brought to the test of the law courts.

Next, adultery is common among these patients, and in some cases I believe divorce has been obtained from a husband suffering from general paralysis whose disease was the cause of his immorality. The courts have so far never looked upon the plea of insanity as a very justifiable one in divorce cases. The general feeling seems to be that adultery is the one thing to be considered, and the contributing cause, insanity, is to be left out. The loss of higher control leads not only to adultery, but to the marriage of general paralytics with persons of immoral character. I have known several general paralytics who have married their mistresses or have married women of notoriously bad character. Besides this, general paralytics with general exaltation take it for granted that any woman will accept them. They, feeling so endowed with riches and honour, only have to seek to get, and under these conditions indecent suggestions or assaults may arise, the man believing that the woman was willing or even encouraging him. More common still in my experience has been indecent exposures. I think in some cases that general paralysis is a good plea for cases of indecent exposure. Indecent assaults on children are made by some men who have lost their higher control. In these cases there is, as a rule, a silly childishness about the acts; they are not brutally violent, but they are often done openly and without attempt at denial or evasion. In epilepsy there may also be fierce eroticism, but the acts are brutally carried out and there is honest denial due to complete loss of consciousness of the acts. The indecent cases of the general paralytic resemble in many ways those which not infrequently are seen in police reports in reference to old men, but in these last there is generally denial, but not of the honest type of the epileptic. It is evasive and easily controverted. In a few cases I have met with sexual perversion and unnatural offences in general paralytics. The patient is generally rather the victim or passive agent, being facile in immorality as in other things. To sum up on this matter, in any case of indecent exposure or assault perpetrated by a middle-aged man be on the look-out for the physical signs of general paralysis.

ACQUISITIVENESS.

As in so many other respects the general paralytic reverts of a simple uncontrolled nature, so it is in relation to property. The child takes what happens to be near him and what at the moment attracts his attention or something which appeals to his simpler desires or appetites. I remember several men who were admitted to Bethlem Hospital after they had been brought before the magistrates for petty thefts. Books from open bookstalls and sheets of music from similar places were the attractions. The attraction of jewellery was great also. The absolute value of things does not appeal so much to the patient as does his value of them. I have known a man take perfectly useless and valueless things for which at the moment he thought he had a distinct use, something which he felt was essential for some great scheme which he was starting. These petty thefts are most common in the earlier stage of the disease; later on the thefts may depend on quite another symptom of the disorder. How can you consider a man to be a thief if he feels that the whole world belongs to him, or that he is so rich that he can repay anyone for anything which he takes. It is thus I have known a man take valuable rings to give to the lady of his love. I have known general paralytics write cheques for large sums on banks at which they had no account. They would not forge a signature, but, fully believing they had money at the bank, would sign cheques. Very serious complications have arisen as the result of patients in the excited stage entering into big speculations, buying recklessly stocks and shares, ordering houses and furniture; as may be imagined, but yet hardly to be expected, I have known a man make a fortune in the earlier stage of this disease. At the time there was a boom—I think it was in nitrates; but any way he bought as freely as he could, and by the time he was in the asylum his speculations had proved a success.

CRIMINAL ACTS.

The criminal acts of general paralytics, as a rule, are not marked by any definite plan, uncontrolled impulse being the general cause, but though not common, yet occasionally general paralytics suffer from hallucinations and may have many of the symptoms of delusional insanity with ideas of persecution, and in such cases patients may be goaded to acts of violence.

CRIMINAL LUNATICS SUFFERING FROM GENERAL PARALYSIS

I have obtained some reports from the English and the Irish criminal lunatic asylums which are of interest, and I will give only the general results. I was surprised to see how rare it is to find criminal lunatics suffering from general paralysis. Dr. G. T. Revington, of Dundrum, tells me that in 20 years he has only had 8 cases of the disease, and Dr. John Baker, of Broadmoor, says that in the 50 years since the opening of the asylum only 58 general paralytics have been admitted. In Dundrum 2 were accused of murder, 2 with sexual crime, the rest with crimes against property. Of the Broadmoor patients, 16 were convicted of murder or serious assaults, 5 were guilty of sexual faults, and 36 of offences against property, including arson, burglary, and the like. As I have already said, it is interesting to find so few criminal lunatic general paralytics. In part this is explained by some of those who have committed thefts being sent to ordinary asylums and never being sent to the State one.

INJURY AND GENERAL PARALYSIS.

Recently a very important practical point has arisen in relationship to the part that injury may play in the production of general paralysis. In questions of compensation for injuries leading to death and also in cases of life insurance it may be contended that injury alone would not have caused the disease. You will recognise that now the great majority of authorities look upon general paralysis and locomotor ataxy as almost certainly associated with, if not fully resulting from, syphilis. Yet I find even such an authority as Dr. F. W. Mott hesitating when asked if it is impossible for general paralysis to arise from accident alone. He, I think, agrees with my experience, which is, that in a very large majority of cases of general paralysis syphilis of long standing can be established, but that this disease alone is not the only factor. The question of heredity comes in, and the illuminating work of Mott inclines one to think that just as with alcoholic poisoning certain persons suffer in their brains while others do so in their general viscera, so with syphilis in some the stress of the disease falls upon the nerve centres, while in others it selects other parts such as the skin or the bones.

To return to the main point, though syphilis is most commonly associated with general paralysis, yet it requires other elements to start the disease. I believe that meat diet and alcohol are factors in many cases, and incidentally I may say that one superintendent of a large asylum told me that with general paralytics he hardly ever gave a meat diet, and as a result the acute phases and the epileptiform seizures had vanished from the asylum.

I have, as most of you must by now know, been in the habit of saying that syphilis seemed to ripen the brain for decay, and that any accident from within or from without might lead to the rottenness or decay. It therefore comes to this:—A man, who many years before had syphilis, was properly treated, and has been a healthy man, receives a blow on his head, which renders him insensible. He may recover from this, but within a few months some alteration is noticed in his conduct. If in one of the services, he gets into trouble by faults of irregularity or unpunctuality. He is irritable and forgetful; slowly the other signs of general paralysis appear and he is invalided. A claim is now made for disability depending on accident. Without the previous syphilis he would not have developed general paralysis, but without the accident he might never have developed it, or, at any rate, not for years. In my opinion, the man ought to be treated as if the accident were the efficient cause of disablement. In the same way in cases in which it is a question of life insurance, I presume a man who has had syphilis would have some addition made to his premium, but if he is following a life which is more than usually associated with risk of even slight accidents, such as being in the army or navy, I think a good deal ought to be added. I do not know of cases which have actually arisen in relationship to these points, but I know that they have arisen in cases in which pension questions had to be considered.

TESTAMENTARY CAPACITY: IMPROBABILITY OF A GENERAL PARALYTIC MAKING A SOUND WILL.

And now I come to a part of my subject—the testamentary capacity of a general paralytic—which has been of great interest to me, as I have on several occasions had to be cross-examined as to my experience and as to my opinion.

At first I fancy many of you would be inclined to say, "Of course, when once established that a man is a general paralytic then his capacity is gone." But you must remember that the law courts have supported wills which have been made in asylums even by patients at the time under the Court of Chancery. So that being of unsound mind does not necessarily prevent the making of a valid will. For testamentary capacity, as I have frequently said, there must be sufficient memory to recognise the property concerned and its relationships, also normal memory of blood relations, freedom from delusions affecting either the property or the relations, and sufficient will power to prevent undue influence.

The dangers in general paralysis are first on the emotional and unstable side, so that the so-called facility comes in, the last impression being followed. The patient will promise the last person whom he met all he possesses and more for no real consideration. The amorous tendency, too, easily leads to the giving largely to unworthy persons. The reckless extravagance depending on delusions of grandeur are very potent influences. The defective memory must also be considered. Here, then, we have commonly a person with defective memory, want of normal recognition of his relations and of his property, and therefore likely to go wrong. He is also very easily influenced. On the first aspect, then, of such cases one is justified in saying it is improbable that a general paralytic will make a good will, but even with all these symptoms he may almost automatically carry out in his will the feelings and judgments of his sane life. Therefore in each case the contents of the will will be found to influence a jury more than your opinion.

WILLS AND LUCID INTERVALS.

Next, it is of great importance to remember that there are in general paralysis frequently periods of complete sanity. I know many, who have not life-long experience of the insane, are inclined to doubt the restoration to sanity of anyone who has been out of his mind, but I know better, and in general paralysis I have seen, even in cases which ended fatally within a short time, perfect lucidity. I remember very well a case which was heard in London some years since in which a man who died of general paralysis made a will some time after he had been in an asylum. He was sent out of the asylum "relieved," and during a period of calm made a will which, though contested, was established. It is very important to remember that it is not in every case that these lucid intervals occur. As a rule the more acute and maniacal the onset the greater the probability of a remission. Though rare, more than one remission may occur, but as a rule I should doubt the capacity of a patient who had had more than one lucid interval. Again, these lucid intervals occur during the earlier stages of the disease, and though I am disinclined ever to be very dogmatic in reference to prognosis in cases of insanity, yet my opinion is that remissions are not to be expected in the second or placid stage of general paralysis, and are impossible in the last or demented stage. This, I think, is a very strong and important point, but one not easily established before a jury. Take such a case as this. I was asked to see a man whom I had once seen before I had diagnosed general paralysis. I found him lying on a mattress on the floor, muttering incoherently. It was impossible to get him to understand a word I said, and I failed to understand anything he said. I heard that he had been in this restless, dirty, and demented stage for some days. I heard that he survived a few weeks and then died. Some time later I was asked to give evidence as to his testamentary capacity at the time of my second visit. I said without hesitation that he was totally incapable of understanding the contents of a will or of duly executing it. Yet his cross was affixed to a document purporting to be his will. I was examined as to the nature of general paralysis, and I was asked if it was not true that in this disease there were lucid intervals. I admitted there were, but only at the earlier

stages. I was asked if I had not assisted in establishing the will of a general paralytic. I admitted this. When trying to explain the differences between the cases I was stopped, and the counsel made it appear that in cases—that is, all or any cases—of general paralysis there might be lucid intervals, and that it was not for a medical expert to say when and how these might occur; the fact was that such intervals did occur, and he maintained that the deceased had during such a period signed the will. The jury agreed with him.

In relationship, then, to testamentary capacity, the ordinary qualifications for capacity must be established, but it must be allowed that there may be periods of complete lucidity during which a proper will may be made. Here I may say that in criminal cases it may be set up by the prosecution that the crime, though perpetrated by a general paralytic, was still done during a period of sanity.

HEART-BLOCK AND NODAL RHYTHM IN THE ACUTE INFECTIONS.

BY JOHN COWAN, M.D. CANTAB.,
PROFESSOR OF MEDICINE, ANDERSON'S COLLEGE MEDICAL SCHOOL; PHYSICIAN, ROYAL INFIRMARY, GLASGOW;
GEOFFREY B. FLEMING, M.B. CANTAB.,
EXTRA DISPENSARY PHYSICIAN, WESTERN INFIRMARY, GLASGOW;
AND
ALEXANDER M. KENNEDY, M.B. GLASG.,
ASSISTANT TO THE ST. MUNGO (NOTMAN) PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW; SENIOR ASSISTANT PATHOLOGIST, ROYAL INFIRMARY, GLASGOW.

IT has been known for more than a century that acute rheumatism is peculiarly prone to affect the pericardium and the valves of the heart, and is, indeed, the most common cause of chronic valvular disease; but it is only within the last few years that its special action upon the cardiac muscle has been recognised, and even now our knowledge of its effects is by no means complete.

Acute rheumatism may produce gross lesions in the connective tissues. The occurrence of subcutaneous nodules was first described by Hillier[1] in 1863 in a case of chorea, and Meynet[2] (1875) and others subsequently recorded their association with acute rheumatism, but these early observers failed to appreciate the full significance of their appearance. In 1881, however, Sir T. Barlow and Warner[3] pointed out the close connexion between the eruption of nodules and the occurrence of acute endocarditis, the presence of large nodules being an almost invariable sign of serious valvular disease, and indicative of a grave prognosis.

It had already been recognised that in certain fatal cases of rheumatic endocarditis the latter seemed insufficient to account for the fatal issue. In some instances pericarditis co-existed and doubtless aided in the progress towards death. But in others it was absent, and the chief clinical phenomenon was a progressive weakness and dilatation of the heart. To these cases Sturges[4] (1894) drew attention in his Lumleian lectures, maintaining that the rheumatic affection of the heart was not merely endocarditis or pericarditis, but *carditis*, all the tissues of the organ being involved in greater or in less degree. It was already known that fatty and granular changes were not infrequently present in the cardiac muscle cells in the acute infections, but it was only in 1899 that Poynton[5] demonstrated the essential rheumatic lesion in the cardiac muscle, the microscopic submiliary nodule, which, though usually smaller, is exactly comparable to the nodules which occur in the subcutaneous tissue.

Within the last few years many observers—Cowan[6] (1903), Geipel[7] (1905), Aschoff[8] (1906), Carey Coombs[9] (1907), and others—have extended the investigation, and have emphasised the importance and the frequency of myocardial lesions in the acute infections. The muscle cells in these diseases are generally abnormal to some extent if the illness has lasted for more than a few days, and submiliary nodules may occur,[10] though they are most common in cases where endocarditis co-exists.

Submiliary nodules are rarely of great size and are generally invisible on naked eye examination. The smaller nodules interfere but little with the adjacent muscle cells, but the latter are always abnormal if the nodule is large.

Microscopic examination shows that the essential lesion is a round-celled infiltration of the interstitial tissue. These infiltrations occur most frequently in the ventricular muscle, especially on the left side. They are usually situated around an arteriole or in its immediate vicinity, and sometimes involve the vessel wall, which may be so swollen that the lumen is almost obliterated. The cells may be few in number and the adjacent muscle apparently normal; but they may be numerous and infiltrate between the muscle cells, which are then more or less degenerate. In most cases the cells are arranged in discrete foci or nodules (Fig. 7), separated from each other by normal tissue; but in others the infiltration is diffuse (Figs. 8 and 9), and much larger areas are involved.

The cells are mainly mononuclear; the majority are evidently lymphocytes, but a few larger cells with a fair amount of protoplasm, which are probably of connective tissue origin, are often present, and occasionally a few polymorphonuclear leucocytes may be seen. In very malignant cases dense aggregations of polymorphonuclear leucocytes, with disintegrated muscle fibres, may be found; in other words, an acute suppurative myocarditis.

The rheumatic submiliary nodule is said to be characteristic (Carey Coombs[11]). The foci are chiefly composed of mononuclear cells superimposed upon a groundwork of fibrin, but also show certain very large cells which are often multinuclear. These may be globular or fusiform in shape, and their protoplasm takes up both acid and basic dyes, so that they appear much darker than the surrounding tissue. We have observed these cells in several cases in the cardiac tissue at the base of inflamed valves, but we have only once (Case 5) found them in interstitial nodules. The arteries, too, in these cases may be thrombosed (Romberg), most often in the vicinity of the auriculo-ventricular junction. We have found arterial thrombosis with arteritis and periarteritis in one case of acute myocarditis.

Cellular infiltrations are very commonly present in the tissues at the bases of inflamed valves, especially the mitral valve, a circumstance which is important on account of their proximity to the primitive tissue of the heart. Bacteria have not hitherto been found in the non-suppurative myocardial nodules, which thus seem to be the result of a local toxæmia. As regards their ultimate fate, the smaller nodules are probably completely absorbed, but it seems certain that the larger lesions may become the foundation of a subsequent fibrosis of the myocardium.

The cardiac muscle in cases of chronic valvular disease is frequently fibroid, patches of sclerosed connective tissue of varying size being scattered here and there throughout the wall. In the majority of cases the fibrosis is the result of arterial occlusion and consequent necrosis of the muscle cells. In mitral disease, however, other causes are often active, and the fibrosis of the tips of the musculi papillares is generally believed to be often the result of a spread of the inflammation from the valves to the papillæ, and not infrequently the connective tissue at the base of the valves is excessive in amount and infiltrates into the adjacent structures. It is evident, too, that some of the more distant fibrous tissue owns a similar origin, and is the result of the healing of the submiliary nodules which we have just described. The patches are peri-arterial in site, multiple and widespread, and individually are of little practical importance, but their multiplicity may interfere considerably with the cardiac action, and they may, accidentally, involve important structures.

It is now generally believed that the rhythm of the heart and the proper sequence of contraction of its various chambers are intimately associated with the integrity of the undifferentiated cells which are present in certain places, the sino-auricular node of Keith and Flack, the auriculo-ventricular node of Tawara, and the auriculo-ventricular bundle of Stanley Kent. It has been repeatedly shown that heart-block may be due to lesions in the auriculo-ventricular

bundle, though in certain cases this has been found to be normal, and the block has been ascribed to vagal lesions.

James Mackenzie [12] has suggested that extra-systoles occur as the result of impulses which arise in the primitive tissue. It has been shown that the normal contractions originate in the immediate vicinity of the sino-auricular node, and presumably in it, and that the region of the auriculo-ventricular tissue is more irritable than the muscle elsewhere, stimulation of the former being followed by a *series* of contractions (Gaskell), while stimulation of the latter only produces an isolated beat.

In chronic heart disease many lesions may be present in the heart—valvular defects, arterial disease, pericardial adhesions, myocardial fibrosis, &c.—and the lesions may be widespread. Variations in the cardiac rhythm are common events in these cases, but it is extremely difficult to disentangle the cause of the abnormal rhythm from the jumble of lesions which is found post mortem, and the maxim concerning *post* and *propter* must be kept in mind. Variations in the cardiac rhythm occur not infrequently in acute disease, and the cardiac lesions are generally more simple and less diffuse than those found in chronic affections; and the relations of cause and effect can, in consequence, be more accurately distinguished. During the last few years we have been engaged in the examination of the heart in such cases, and now report the results in five instances.

Heart-Block.

CASE 1.—The patient, a girl aged 10, was admitted into Ruchill Fever Hospital on Feb. 5th, 1910, suffering from diphtheria of five days' duration. Her previous health had not been good, but no details could be obtained. She had had attacks of measles, whooping-cough, and chicken-pox.

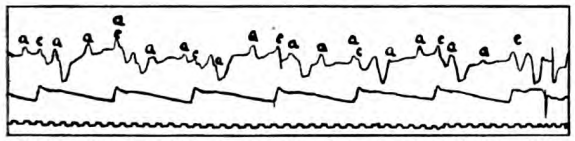
The girl's illness had commenced on Feb. 1st, the initial symptoms being headache, vomiting, and sore-throat. On admission she was found to be a poorly nourished and neglected child. The throat and pharynx were congested, the right tonsil was slightly ulcerated, and there was a considerable amount of loose membrane on the back of the throat. The toxæmia was severe, but the viscera seemed normal, and the urine did not contain albumin. Fever was slight, 99·2°F.

For the next two days the child's progress seemed satisfactory, and she was bright and cheery; but on the 9th she became dull and listless, and vomiting ensued; symptoms of palatal palsy made their appearance, and the heart dilated. On the 10th the vomiting persisted, and the child was restless and irritable. The weakness increased, and she died in the evening from cardiac failure.

The heart on admission seemed normal, but evidence of dilatation was manifest on Feb. 9th. There was widespread pulsation over the præcordium and very frequent and obvious pulsation in the neck above the clavicles. The first sound was somewhat short and muffled, and the second was occasionally reduplicated. No sounds corresponding to the auricular contractions could be heard. The pulse-rate during her residence was generally infrequent and varied greatly at different times. On admission it numbered 96; on the 6th 62; on the 7th it varied between 88 and 40; on the 8th between 80 and 52; on the 9th between 72 and 48; and on the day of death between 62 and 40.

Tracings were obtained on the three days immediately preceding death, and all showed complete heart-block, the auricular contractions numbering 100–110, and the ventricular 46–54 per minute. (Fig. 1.)

FIG. 1.



CASE 1.—Complete heart-block. Auricular rate about 110, ventricular rate about 46.

Necropsy.—The heart alone was examined post mortem. It was distinctly dilated and the muscle was rather pale. The cusps of the valves were healthy, but the auriculo-ventricular valves were slightly dilated.

Microscopic examination of the *a.-v.* node and bundle [13] showed that the node and the upper part of the bundle were involved in a well-marked acute inflammatory process (Figs. 7 and 8). The capillaries were notably congested and many cellular collections were present. The cells were chiefly mononuclear, and mainly lymphocytes, but a fair number of polymorphonuclear cells were also found. The bundle was diffusely infiltrated in many places, and its fibres distinctly separated from each other; and at one place about its middle considerably damaged by a larger nodule. The lower part of the bundle and its branches seemed normal.

The cardiac muscle generally showed evidence of interstitial inflammation, both focal and diffuse.

The vagus nerves were examined by Donnaggio's second method for early degenerative changes, but were found to be normal.

CASE 2.—The patient, a man aged 26 years, was admitted into hospital on June 5th, 1909, complaining of weakness and of breathlessness on exertion of some months' duration.

The patient's health had been good save for occasional "growing pains" and an attack of tonsillitis in boyhood, and gonorrhœa in the early part of 1903, until an attack of enteric fever later in the same ear, for which he was in hospital in Japan for about three months. He never regained his former health, and his feet were often swollen at night, but he was able to work until July 1908, when he was thrown out of employment by the failure of his firm. He stayed at home in fairly comfortable circumstances until he procured a new situation on Feb. 19th, 1909. In the early part of February he had caught cold and he was feeling "run down" when he commenced his new work. This entailed a daily walk of four miles, and he felt exhausted at night, and also during the day when walking uphill; but though he steadily became weaker he continued at his post until six weeks before admission, when he was compelled to go to bed. His cough, accompanied by a slight mucoid spit, persisted from February until May. He had frequent attacks of shivering at night after getting home; they were fairly severe, and lasted for 15 to 20 minutes, and he felt hot after he got into bed, and often sweated profusely in the early morning. About a fortnight before admission his right forearm and elbow became sore to the touch and on movement, and this continued for a few days Four days before admission the left hip and ankle became painful, and this still persisted.

On admission the patient was found to be a thin, pale, badly nourished man, with flabby muscles and little subcutaneous fat. The left hip and ankle were painful and tender, and there was a small tender area of induration on the back of the left forearm. The right calf was, he said, painful, but nothing abnormal could be detected. There were several minute ecchymoses on the conjunctival surface of the right lower eyelid, and a fairly large one on the conjunctiva of the left bulb, while ophthalmoscopic examination revealed a medium-sized flame-shaped hæmorrhage on the course of the left superior temporal vein. The lungs were normal, the tongue was clean, and digestion good; the liver and spleen were slightly enlarged; the urine contained a small amount of albumin. The heart was but little enlarged, though there was a well-marked mitral systolic murmur. The pulse was frequent, regular, small, and soft; and he was slightly fevered at night.

Progress after admission was slowly but continuously in the wrong direction. Many embolisms occurred, chiefly in the limbs, but once, at any rate, in the spleen and twice in the kidneys. He had several "faint turns" of a few minutes' duration without obvious cause. The weakness increased, and after the middle of July œdema was more or less continually present in the legs. There were occasional rigors and generally profuse sweats at night. On August 25th a left hemiplegia occurred, and he died on August 29th.

The pulse during the patient's residence in hospital was always regular until immediately before death; and the venous curves were normal, save that the *a.-c.* interval was invariably prolonged, measuring about 0·25 sec. and never touching 0·2 sec. or 0·3 sec.

Necropsy.—Post-mortem examination revealed an acute endocarditis of the mitral valve. Two emboli were present in the right middle cerebral arteries, and septic infarctions were present in the left kidney and the spleen; from the latter the pneumococcus and B. coli communis were isolated in culture. Blood cultures during life had proved sterile.

The mitral valve was dilated. Numerous vegetations were present on the cusps, some small and wart-like, others long and luxuriant. The endocardium of the left auricle was thick and opaque, and a few minute granulations were present on the contra-fossal wall immediately above the valve; the endocardium at this point was notably thickened. There was no evidence of mural implication elsewhere.

Microscopic examination of the *a.-v.* node and bundle revealed well-marked congestion. The node was otherwise normal, though two small foci of round cells were found in the auricular muscle in its immediate vicinity. The bundle was involved in three separate places by foci of the same kind. The first was of small size and was situated immediately below the node; the second, which was considerably larger, was found a little lower down, between the auricular muscle and the bundle, and implicated both; the third, of fair size, occupied the central part of the bundle, and occurred immediately above the point where it passed through the central fibrous body. The cells were all mononuclear and chiefly lymphocytes. The fibres of the *a.-v.* bundle seemed normal, save in the immediate vicinity of the two larger foci, where they were evidently degenerate. The fibrous tissue of the bundle was not excessive in amount. The cardiac muscle generally showed evidence of interstitial myocarditis in an early stage, and the muscle fibres in some of the patches were degenerate.

The majority of the cases of heart-block which have been recorded have been associated with chronic lesions of the *a.-v.* bundle, the most common cause being fibrosis with or without calcification (Lewis [14]). In 1905, however, James Mackenzie [15] reported the transient occurrence of the milder grades of block in cases of acute rheumatism and influenza; and in 1908 several cases were reported in which full heart-block was found to be due to acute lesions. In one (Jellinek and Cooper [16]), where death resulted from acute gonorrhœal endocarditis, there was an acute necrosis of the interventricular septum; in a second case (James [17]), there were ulcerative endocarditis and an ulcer of the interventricular septum immediately beneath and posterior to the membranous septum; in a third (Gerhardt [18]) the patient suffered from rheumatic fever, followed quickly by enteric fever; inflammatory lesions were found in the *a.-v.* bundle. More recently Magnus Alsleben [19] has reported a case of diphtheria where full heart-block was due to a severe parenchymatous degeneration of the *a.-v.* bundle.

A partial or full heart-block is by no means of rare

[12] Diseases of the Heart, London, 1908.

[13] The *a.-v.* node and bundle in these cases were examined in serial sections, *every section* through which the *a.-v.* node and bundle passed being examined.

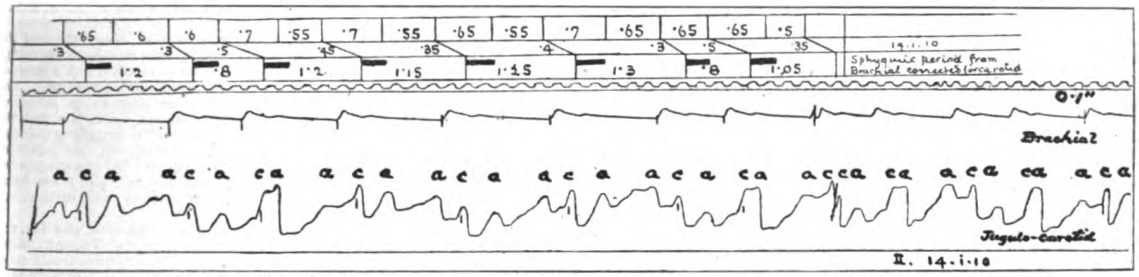
occurrence in acute disease. Ribl [20] has reported a case in which full heart-block seemed to have followed an attack of acute rheumatism. Griffith [21] has twice observed heart-block in gonococcic infections; Wenckebach [22] has seen it in influenza; Hay [23] has found it in diphtheria and in a gonococcic infection; and Magnus Alsleben [24] in pneumonia and enteric fever. Transient defects are not uncommon in acute rheumatic endocarditis, and we have now observed at least five

FIG. 2.



Partial heart block. The ventricular contractions (1-2) are completed before the succeeding auricular contractions (2-4) occur. Conduction is, however, so defective after the fourth auricular contraction that the third ventricular contraction is not completed before the fifth auricular contraction ensues.

examples. In one the defect persisted for nearly four weeks; in another it disappeared after six days, recurred three days later, and again lasted for six days. In none of these cases was there complete heart-block, but in one the ventricles only responded to every second auricular contraction. All the cases made good recoveries, and in one alone was the ultimate valvular lesion severe. We have observed three other cases in which a transient defect occurred. One was a case of enteric fever, another of diphtheria, the third of scarlatina. In none was there any evidence of endocarditis, and in all recovery was good.

Defects in conductivity can only be recognised by means of graphic methods, though they are, of course, suggested by extreme slowness or irregularity of the pulse. In one of our cases, however, the auscultatory phenomena were striking. A systolic murmur was audible at the apex. The ventricular contractions were infrequent and irregular, but occasionally two or three beats occurred in more rapid succession. With the isolated contractions the mitral murmur was long and loud, but when a series of frequent contractions obtained the murmur accompanying the second and third beats was much shorter and less distinct. The explanation was obvious on examination of the jugulo-carotid curves. (Fig. 2.) Conductivity was defective, but after the long pauses was sufficiently good to permit the completion of the ventricular contraction before the commencement of the succeeding auricular contraction; but, when the pause was short, became so defective and prolonged that the ventricular contraction coincided with the succeeding auricular contraction. The regurgitation into the auricle was in consequence minimal, and the murmur became shorter and less distinct.

The causes of heart-block are numerous and not necessarily associated with lesions of the *a-v.* tissues, as it has been produced experimentally by the administration of various drugs (digitalis, aconitine, adrenalin, muscarin physostigmine), by the induction of asphyxia, and by vagus stimulation. It thus seems probable that nervous and toxic influences may produce heart-block in man without there being any lesion in the *a.-v.* tissues, but so far only one case has been recorded (Holst and Monrad-Krohn) with full post-mortem examination and graphic records in which the nervous origin seems definitely proved. In Case 1 of our series the presence of palatal palsy seems to point to a nervous origin of the block, but the post-mortem examination showed that the vagus nerves were normal. In our second diphtheritic case there was no evidence of any paralysis.

FIG. 3.

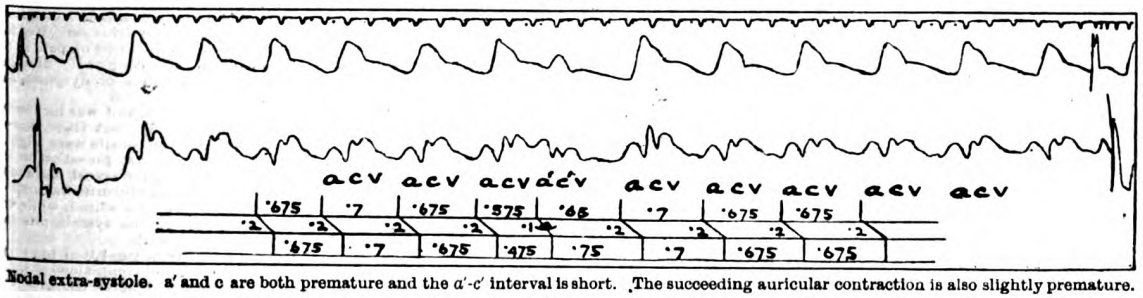
FIG. 5.



Nodal extra-systole. a' and c are both premature and the *a'-c'* interval is short. The succeeding auricular contraction is also slightly premature.

Nodal Rhythm.

CASE 3.—The patient, a man, aged 24, was admitted into hospital on July 15th, 1909. His previous health had been good, save for attacks of measles and enteric fever in childhood; but he was often troubled with gumboils, and was frequently wetted at his work.

The patient's present illness dated from July 1st, when he had had

[20] Zeitschrift für Experimentelle Pathologie und Therapie, Berlin, 1905, vol. ii., p. 83.

[21] Personal communication.

[22] Arrhythmia of the Heart, Edinburgh, 1904.

[24] Loc. cit.

one of his molars extracted on account of a gumboil from which he had suffered for a day or two. In the evening he felt sick and shivery, and probably was fevered. These symptoms continued, and on the afternoon of July 4th he had a definite rigor. On the 7th he felt better, and on the 8th he went to Ardrossan, walking from the station to the house at which he stayed (two miles). After this he improved until the 12th, though he had a slight cough after the 6th, with discomfort in the left chest. But on the 12th he had to go to bed as the pain in the side became worse and was much intensified on coughing. The left arm, too, was stiff, and he was very breathless and had to sit up in bed at night. On the evening of the 13th he was better, and able to sleep quietly lying down.

On July 14th the man felt so well that he dressed and went downstairs to breakfast, which he did without any difficulty or assistance; after breakfast he sat down on a chair, and on attempting to rise an hour later found that his legs were powerless and "had no feeling" in them. He had to be carried back to bed.

On admission the patient was found to be notably emaciated, with small muscles and scanty subcutaneous fat. His complexion was somewhat sallow and his expression anxious, while he had to be propped up in bed on account of breathlessness. The skin was hot and dry and there was a little œdema of the feet and slight pitting with the stethoscope on auscultation over the cardiac area. He was slightly fevered at night. The patient, though weak, was quite clear mentally, spoke correctly, and answered questions accurately and sharply. He had little power in his legs, but was able to pull up both knees, though he was unable to move the toes of the right foot. The movements were more free on the left side. There was considerable anæsthesia in both legs. Power was perhaps deficient to some slight extent in the left arm, but in the right was good; and sensation seemed normal. The right pupil was slightly smaller than the left; both reacted to light and on accommodation.

The tongue was dry and coated, many of the teeth were absent, and most of the remainder were carious, and the mouth generally was very foul. The pulse was soft, regular, and infrequent. Palpation of the apex beat, which was full and widespread, showed that every other beat was missed at the radial, the cardiac action being regularly coupled. A systolic murmur was audible all over the cardiac area. It was heard best at the apex, where it was long and soft, replacing and running out of the first sound; the second sound was not audible here. The respirations were difficult and cyclic, but without any full apnœa. A consolidation was found in the upper part of the right chest and in the left lower axilla friction sounds were audible. The urine contained a trace of albumin.

For a few days the patient's general condition improved slightly. The coupled rhythm ceased on the 16th, and he rested fairly well at night. On the 17th movement was more free in the left leg, but the palsy below the right knee persisted. About midnight on the 18th he was noticed to be restless and was found to be semi-conscious and unable to say more than "yes," and there was a well-marked full right hemiplegia. He gradually became weaker and more comatose, and he died with cardiac failure on July 27th, 1909.

The pulse remained "single" until the day of death, when it was noticed to be "coupled" again for a short time. The tracings, which were obtained in this case during the coupled rhythm showed that there was a slight increase of the *a.-c.* interval (0·25 sec.) with the first or larger beat of the couple, and that the second or smaller beat was a ventricular extra-systole which did not interfere with the auricular rhythm. Tracings of the "single" pulse obtained on July 23rd showed a regular pulse and a very short *a.-c.* interval measuring little more than 0·05 sec.

Necropsy.—Post-mortem examination revealed an acute ulcerative endocarditis of the mitral valve, engrafted on a lesion of older standing. The upper and middle lobes of the right lung were solid from a somewhat chronic pneumonia, and there were numerous infarcts in the spleen and kidneys. The left middle cerebral artery was occluded by a large pale embolus which resembled the vegetations on the mitral valve, and was associated with a very extensive softening. Streptococci were isolated on culture from the spleen. No blood cultures were made during life.

The mitral valve was stenosed, the cusps being notably shortened, the chordæ tendineæ short and thick, and the tips of the papillary muscles fibrous. There was well-marked evidence of fibrosis spreading upwards from the bases of the cusps in the direction of the central fibrous body of the heart. Enormous soft recent vegetations almost occluded the valve, and there were in addition extensive ulceration and perforation of the anterior mitral cusp. There was no evidence of any acute mural endocarditis; but the endocardium of the left auricle was thick and opaque, with a special area of thickening about as large as a shilling on the contra-fossal wall just above the valve.

Microscopic examination of the *a.-v.* tissues revealed considerable congestion of the tissues generally. The node was the site of a profound inflammatory disturbance, many focal collections of round cells being present, as well as, in places, a diffuse infiltration. (Fig. 9.) The fibres of the *a.-v.* node were probably normal, and there was no evidence of old-standing fibrosis. The walls of a microscopic artery were infiltrated with round cells, though the lumen was patent; the other vessels seemed normal. The intensity of the lesions varied at different levels, but the whole of the node was more or less affected. The bundle, on the other hand, was not implicated, save at one place immediately below the node, where one or two small foci in the auricular muscle immediately adjoining it passed in for a short distance between a few of its fibres.

There was a well-marked myocarditis, involving both ventricle and auricle, but it was only extreme at the base of the mitral valve, and in the auricular sections immediately above the node itself.

CASE 4.—The patient, a man, aged 42, was admitted to hospital on Jan. 31st, 1911, complaining of breathlessness and of swelling of the feet and legs of two or three months' duration.

He had always enjoyed good health prior to the onset of his present illness, save for pneumonia at the age of 30, and attacks of measles in childhood and at the age of 32. He had habitually used tobacco and alcohol to excess.

In the preceding April he had caught cold and had never been well since. The cough and spit persisted and he lost appetite and felt weak and unable to do his work. In July he noticed that his feet were sometimes swollen at night, and he began to be very breathless on exertion. In August the œdema became permanent and, steadily increasing in amount, soon compelled him to remain in bed. In December he one day suddenly felt severe pain in his right side and spat blood in considerable quantities for some weeks. He had to be propped up in bed on account of breathlessness, the spit and the œdema steadily increased in amount, and his general strength rapidly failed. In January he attempted a short walk, but fell down in a faint on the pavement.

On admission the patient was extremely ill. He sat bolt upright in bed, coughing continually and spitting up large quantities of watery mucoid material. Œdema was universal and very marked in the legs and scrotum. Detailed examination was impossible, but evidence was found of a consolidation of the middle lobe of the right lung and of pleurisy on the same side. The heart was enlarged and double aortic murmurs were audible down the sternum. Progress was continually in the wrong direction. The hæmoptysis recurred, the dyspnœa and œdema increased, exhaustion became more and more extreme, and he died suddenly on Feb. 5th.

The respiratory difficulty prevented continuous observation of the cardiac irregularities. The pulse on admission was notably irregular in rhythm from the frequent occurrence of extra-systoles, but a series of 20 or 30 fairly regular beats of slow rate occasionally obtained. The extra-systoles were sometimes isolated and sometimes in salvoes of 2, 3, or 4. On Feb. 1st the same state continued. On the 2nd the pulse was very irregular and very mobile, a bout of coughing quickening the rate from about 90 to about 120–130, the frequent rate persisting for a minute or two after the cough ceased. On the 3rd the irregularity was more marked, but on the 4th had disappeared, the pulse being quite regular with a rate of 110–120; alternation was distinct. It remained regular until death.

Jugulo-carotid curves were only obtained on Feb. 2nd and 4th, and are somewhat deformed by the respiratory movements. Tracings on the 2nd show the irregularity of the pulse, and the jugulo-carotid curve demonstrates that while the *a.-c.* interval in the case of the large beats is of normal length, it is much shorter with the extra-systoles, varying between 0·10 sec. and 0·15 sec. On the 4th, when the rhythm was regular but more frequent, the *a.-c.* interval is always short, and measures 0·10 sec. (Fig. 3). The tracings thus seem to show that on the 2nd extra-systoles were arising frequently in the vicinity of the node, the sinus rhythm, however, on the whole predominating; while on the 4th the pacemaker had changed, the sinus influence had been lost, and *every* contraction originated in the auriculo-ventricular node.

Necropsy.—On post-mortem examination the heart was found to be greatly enlarged, weighing 25½ ounces. The aortic valve was incompetent, the septal cusp having a fairly large perforation with well-defined margins a little below its free border. All the cusps showed some small recent warty vegetations, but were not thickened. The other valves were not affected, but the auriculo-ventricular valves were dilated. Two patches of superficial mural fibrosis were present in the left ventricle. One, which was small, was situated near the apex. The other, which measured about ½ in. in diameter, was situated on the interventricular septum underneath the anterior mitral cusp, its anterior border being fully ½ in. behind the posterior border of the pars membranacea. The coronary arteries and the aorta were but little abnormal.

A small abscess was found in the lower lobe of the right lung as well as a large infarction; both pleuræ were adherent. The liver was adherent to the diaphragm, and there was a well-marked perisplenitis. The kidneys showed slight evidences of arterio-sclerotic fibrosis and one or two small infarcts.

Microscopic examination showed that the *a.-v.* node was involved in an acute inflammatory process. Many focal cellular collections were present and some small diffuse infiltrations, the fibres in their vicinity showing granular degeneration. The reaction was best marked in the upper portion of the node and in the part which was nearest to the base of the mitral valve. The cells were chiefly mononuclear and mainly lymphocytes, with only an occasional polymorphonuclear leucocyte. The *a.-v.* bundle was not definitely affected, but was slightly implicated by a nodule in the cardiac muscle immediately beneath and posterior to it. The fibrous tissue around the bundle appeared excessive in amount and showed traces of calcification.

The cardiac muscle generally showed evidences of cloudy swelling and a few nodules, which were most numerous at the base of the mitral valve and in the auricular muscle just above the node.

CASE 5.—The patient, a girl, aged 10, was admitted to hospital on June 10th, 1911, complaining of shortness of breath and of swelling of the feet of a week's duration.

The girl had enjoyed good health, with the exception of three attacks of "measles," until about two months before admission, when she was noticed to be taking her food badly and to be losing flesh, and to be disinclined for her usual play. She continued, however, to go to school until the beginning of June, when she contracted a cough unaccompanied by spit and became short of breath on exertion. Her face and feet were noticed to be swollen, and she complained of pain in the abdomen and beneath the sternum when she coughed. She had sometimes to sit upright in bed at night on account of dyspnœa, and in the mornings she complained of headache.

On admission the child looked ill and exhausted, and was inclined to be drowsy. The face was pallid and looked puffy, but there was no œdema. The tongue was thickly coated and the tonsils were slightly enlarged. Both hearts were enlarged, and there was pulsation in the second, third, fourth, fifth, and sixth interspaces, the apical impulse in the fifth space being diffuse. A long soft blowing murmur was audible at the apex, partly replacing and following the first sound, while the second sound was "doubled." Over the xiphoid the systolic murmur was loud and harsh and resembled a friction sound.

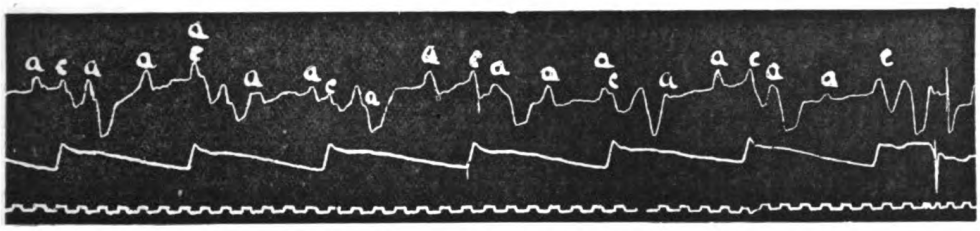
During the next fortnight the patient's general condition improved slightly, but she still looked ill and exhausted, and complained at times of substernal pain. An urticarial rash appeared upon the 24th and persisted for a few days. On the 29th pericardial friction was well marked and a small pleural effusion was discovered at the base of the left lung. In the beginning of July the symptoms became more serious, and she grew easily weaker and sometimes sweated profusely at night. A crop of minute subcutaneous nodules developed on the backs of the hands and persisted for a few days. On the 14th vomiting set in and continued severely for the next three days. Exhaustion became more extreme, and she died on July 22nd.

The nature of the infection was obscure. There was no history of arthritis, and the joints were never swollen or painful during her residence, and the tonsils, though large, were not acutely inflamed. She was habitually slightly fevered at night, but the temperature only once rose above 101° F., and was more usually under 100°. The leucocyte count

varied between 8000 and 23,000. No other foci of infection were discovered, and the symptoms seemed to point to a rheumatic infection of the heart without arthritis.

The pulse on admission was regular, small, and extremely soft. At first the rate was 100–110, but it steadily increased, and for the last two weeks of her illness never ran below 120, though it only numbered 140 on two occasions. Tracings were obtained on several occasions and were regular and normal until July 3rd, when a ventricular extra-systole was recorded. During the succeeding days the pulse was often slightly irregular from extra-systoles, but no satisfactory curves were obtained until July 17th (Fig. 4). The respiratory movements were frequent and deformed (+) every alternate pulse beat, but *a.-c.-v.* are distinct in the intervening contractions, and the *a.-c.* interval regularly measures 0·10 sec. A tracing on July 22nd again shows a regular pulse with an *a.-c.* interval of the same length.

FIG. 6.



(Reproduced from *Heart*, a facsimile of the drum tracing shown in Fig. 1 on a small scale.)

Necropsy.—Post-mortem examination revealed a well-marked subacute pericarditis, the two layers of the pericardium being closely adherent to each other by fibrinous adhesions over the front of the heart, but only slightly over the posterior surface. The parietal pericardium was adherent in several places to the chest wall. The heart generally was enlarged. The mitral and tricuspid valves were both dilated and showed rows of recent pearly vegetations upon their auricular surfaces.

One or two caseous glands were found at the root of the right lung. Both pleuræ showed evidences of subacute pleurisy.

Microscopic examination showed a well-marked interstitial myocarditis. The nodules varied somewhat in their character. The majority were composed of mononuclear cells with a few polymorphonuclear leucocytes; others were of the "rheumatic" type, consisting chiefly of multinucleated giant cells with only an occasional lymphocyte; and a few were "mixed" with a few giant cells, many lymphocytes and an occasional polymorphonuclear leucocyte. The muscle cells in the vicinity were evidently degenerate.

The lesions were most extreme in the neighbourhood of the mitral and tricuspid valves. The *a.-v.* bundle was involved in a large focus which, occurring near the tricuspid valve, infiltrated the bundle for a short distance. The *a.-v.* node was notably affected; none of the infiltrating cells, however, were multinucleated. The capillaries were extremely congested, and the lymphatic vessels could be seen plugged with solid masses of lymphocytes. (Fig. 10.) The principal vein of the node showed an acute phlebitis and periphlebitis. (Fig. 11.) The majority of the cells in the wall of the vein were lymphocytes, but a considerable number of polymorphonuclear cells were also present, and at one place a group of giant cells. Around the vein the polymorphonuclear cells were almost as numerous as the lymphocytes, and infiltrated the auricular muscle immediately above it. The greater part of the phlebitis was above the node. Just before the vein left the node it was joined by a moderately large branch, and the vein above the junction was thrombosed, the thrombus consisting of a fibrinous matrix with numerous red cells and abundant polymorphonuclear leucocytes. (Fig. 12.) The thrombus was attached to the side of the vein, but did not completely occlude it, and could be traced through several sections.

In 1907 James Mackenzie[25] suggested that extra-systoles might arise in the *a.-v.* node (nodal extra-systoles). In certain extra-systoles the tracings show that the auricle contracts at a time when the ventricle is already in contraction and the auriculo-ventricular valves are shut. In the majority of these cases careful measurement demonstrates that the auricular rhythm is unchanged and that the coincident contraction of auricle and ventricle is due to a ventricular extra-systole occurring immediately before the regular sinus contraction of the auricle. In some cases, however, both the auricular and ventricular contractions are premature (Fig. 5), and, as in auricular extra-systoles, the prematurity of the contraction entails defective conduction, the extra-systole cannot originate in the auricle, and both auricle and ventricle must respond to a common stimulus arising between them. It seems probable that Mackenzie's theory should be slightly amplified.

The *a.-c.* interval in jugulo-carotid tracings measures in the normal individual about 0·20 sec., being slightly shorter if the pulse-rate is frequent. During the *a.-c.* interval five events occur: (1) the auricular systole which lasts for about 0·10 sec.; (2) the passage of the stimulus from auricle to ventricle; (3) the latent period of ventricular contraction; (4) the period of ventricular systole prior to the opening of the aortic cusps; (5) the transmission of the aortic wave to the carotid artery. The average period between the commencement of ventricular systole and the appearance of the carotid wave in the neck (4 and 5) is 0·066 sec. (0·03 sec.–0·11 sec.), while the commencement of auricular systole

FIG. 7.

practically coincides with the appearance of the *a* wave in the jugulo-carotid tracing. The presphygmic interval and the transmission time are invariably lengthened in premature systoles, and it thus seems probable that whenever the *a.-c.* interval in the jugulo-carotid curve measures less than 0·10 sec. the auricle and ventricle respond to a common stimulus which arises between them.

In Cases 3, 4, and 5 the *a.-c.* interval is short. In Case 3 it measures 0·06 sec.; in Case 4, 0·10 sec.; in Case 5, 0·10 sec. The rhythm of the heart in these cases is almost absolutely regular, and regular action of the heart probably denotes a common site of origin for all the contractions; so the conclusion is reached that the heart in these cases was responding to stimuli which arose regularly in an abnormal site, between the auricle and the ventricle (nodal rhythm). In Case 4 the earlier tracings make the conclusion even more certain, for they show that at one time extra-systoles were arising in the vicinity of the node, though the majority of the beats were in response to sinus stimuli.

We have been unable to find any tracings of a similar kind in the literature, with the exception of a case (Case 10) recorded by one of us in the *Quarterly Journal of Medicine*.[26] The pulse in this patient numbered 66–80, and the *a.-c.* interval invariably measured 0·10 sec. This patient made a fair recovery from his symptoms, which were chronic in character.

This conception of a nodal rhythm is confirmed, if not proved, by the series of electro-cardiographic curves which have been recorded by Lewis[27] in cases of paroxysmal tachycardia. In Fig. 26 a short paroxysm is shown. In the earlier part of the tracing the normal P.R.T. waves are well marked, the P.–R. interval being 0·14 sec. During the paroxysm the waves R. and T. are similar to those occurring during the normal rhythm, but the wave P. is *inverted*, which strongly suggests that the wave of contraction in the auricular muscle has travelled in a direction the reverse of the normal —i.e., from below upwards (Lewis); while the P.-R. interval is now only 0·08 sec. At the end of the tracing the normal rhythm is resumed.

Paroxysmal tachycardia not infrequently shows jugulo-carotid tracings similar to those which we have described in Cases 3, 4, and 5, but the pulse-rate is much more frequent, numbering in three curves which we have obtained, 160, 182, and 214. In all these cases auricular contractions regularly preceded the ventricular contractions by a period which did not exceed 0·10 sec. It is well known that the *a.-c.* interval varies to some extent in its duration even in the same individual, and is shorter when the heart is beating frequently than it is when the pulse-rate is slow, but in normal rhythms P. is never inverted.

The cases which we have reported cannot, however, be regarded as examples of paroxysmal tachycardia. In all three the sequence of events was similar, the tracings showing at first a normal rhythm interrupted by occasional extra-systoles, and preceding death a *regular* more frequent action with a short *a.-c.* interval. In no case was the tachycardia excessive or paroxysmal or the onset of the new rhythm abrupt. It seems probable that nodal rhythm is not so uncommon as it would appear to be from the scarcity of records, for an ante-mortem rise in the pulse-rate attracts little special attention, though an infrequent or an irregular pulse does not escape investigation.

The inception of heart-block or nodal rhythm may conceivably be the proximate cause of death, for the mechanical difficulty under which the heart labours in these rhythms must be very considerable, the synchronous contraction of auricles and ventricles throwing the auricular blood backwards into the veins, and lessening in considerable degree the ventricular content and output. The blood pressure in these cases is in consequence always low and the pulse is always small. The serious import of paroxysmal tachycardia is now thoroughly recognised, for the continuance of a paroxysm for more than a few hours is known to lead rapidly to dilatation of the heart, a result which will ensue the more readily in cases where the valves are acutely inflamed and the cardiac muscle degenerate and weak.

Summary.—In a case of diphtheria, with full heart-block, the *a.-v.* bundle and node were found to be involved in an acute inflammatory process, and similar lesions were present in the *a.-v.* bundle in a case of malignant endocarditis in which conductivity was defective. In three cases of acute endocarditis, with nodal rhythm, the *a.-v.* node was acutely inflamed, the bundle being only and but slightly affected in one instance.

Glasgow.

[26] Cowan and Ritchie: Coupled Rhythms of the Heart, 1910, vol. iv., p. 55. Belski (Zeitschrift für Klinische Medizin, Berlin, 1909, vol. lxvii., p. 515) has reported several cases (acute rheumatism, scarlet fever, enteric fever) in which he considered that the heart was contracting in response to stimuli which originated in the *a.-v.* tissues. His tracings show a rhythmical appearance of nodal or ventricular extra-systoles, often in groups of 2, 3, or 4 (Belski).

ON THE USE OF SALVARSAN IN THE TREATMENT OF SYPHILIS.

BY ARTHUR FOERSTER, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE RESIDENT MEDICAL OFFICER, MALE LOCK HOSPITAL, LONDON.

SELDOM has a new remedy received such general attention as has Professor Ehrlich's salvarsan, and thus a *résumé* of my experience with this drug may be of interest. Thanks to my former chief, Mr. J. Ernest Lane, I have been able to apply this new therapy on the large clinical material of the London Lock Hospital since the beginning of August, 1910. Some of the cases have thus been under observation for more than a year. With few exceptions they were men who had acquired syphilis, and hence my remarks will be confined to the treatment of acquired syphilis by the new remedy. If I refrain from giving statistics it is because the plan of treatment gradually underwent changes which the evolution of the new therapy rendered necessary, and therefore the later cases were treated in a manner different from that employed for the earlier ones.

Technique.

I have always avoided the use of subcutaneous injections on theoretical grounds, and it is difficult to understand why they should have been used to a considerable extent. The object-lesson of the subcutaneous mercurial injections, the demonstration of Professor Orth at the meeting held in Koenigsberg (September, 1910), and the researches of Martius on the necrosing influence of salvarsan upon human tissues should have led everybody to discard this mode of administration, which is responsible for a good deal of the discredit cast upon the new remedy. I have seen abscesses due to this method in patients who had been injected in London, Aix-la-Chapelle, and South Africa. Some of these abscesses were discharging five, and even six, months after the "accident," despite incision. They are so tedious and troublesome that nothing short of complete excision—as if they were tumours—seems sufficient to cope with them. Therapeutically these cases were failures, little, if any, of the salvarsan having been absorbed. It is hardly necessary to mention that these patients were unwilling to have any further salvarsan treatment.

The intramuscular method was adopted exclusively in the earlier cases. The high dilutions employed at that time on the continent were avoided, as I could only see in them a factor favourable to the production of abscesses and of pain. My efforts to reduce the amount of fluid to be injected, and to obtain a clear solution, led me to the preparation of acid solutions of very small bulk (6 c.c. as a rule). This method, which is practically the same as Duhot's, whose work I was not conversant with at the time, appears to me to deserve preference over all other forms of intramuscular administration. Of other methods tried by me, the suspensions of Michaelis and of Wechselmann are notoriously unsatisfactory (Ehrlich, Rille, &c.), and the alkaline solutions tend to give excessive pain. Emulsions, of which I have tried self-made emulsions in olive oil, appeared to be the least painful, but also to be therapeutically inferior to the acid injections.

This form of salvarsan administration is the most effective of all, in my experience—a view which is now also endorsed by Ehrlich,[1] who so fervently pleaded for the intravenous method about a year ago.[2] I have not observed an abscess with these intramuscular injections, which should be given near Barthélemy's point. The pain is usually severe after these injections, and lameness, lasting frequently a fortnight,

[1] Münchener Medicinische Wochenschrift, 1911, No. 47.
[2] Ibid., No. 1.

was noted repeatedly. Attempts to alleviate the suffering by adding a local anæsthetic, such as cocaine, to the salvarsan mixture are perfectly futile, because the effect of the local anæsthetic has long worn off before the salvarsan pain has reached its height. The only efficient way of diminishing the pain produced is to give morphia, as has been the practice of Duhot.

It is this respect for the patient's comfort which compels one to prefer the intravenous method. Theoretically this procedure appears to be the most suitable one for a *therapia sterilisans magna* in the meaning of Ehrlich, and thus it was taken up with zeal, despite its greater technical difficulties. It is nowadays the routine, and there is little probability that it will lose its favour. For the introduction of the drug into the blood stream either gravity or pressure is resorted to. Thus one either requires a simple infusion apparatus, as used from the beginning by Weintraud, or a suitable syringe, as indicated by Ehrlich and Schreiber. All the more or less complicated devices now on the market, with their additional taps, bellows, receptacles, &c., are more apt to hamper than to facilitate the operation. Personally, I have no hesitation in giving the infusion apparatus the preference. The only difficult point about the whole intervention is the introduction of the needle into the vein, and even the most skilful will meet with cases where he is compelled to make more than one attempt or even to expose the vein before he succeeds in introducing the needle correctly, of which success the following signs are the most important: (1) absence of pain or swelling when one allows the liquid to flow; (2) a wave-like sensation along the vein in a centripetal direction. This latter sign is absolutely characteristic of the correctness of the manipulation. If one uses the gravity method and allows saline only or water to flow in the beginning it is impossible to injure the patient's arm with these precautions. Attempts to ascertain the correctness of the position of the needle by moving it about after it has entered the vein or by allowing the blood to run back into a special "window" inserted in the tubing are to be condemned. In the former case one tends to injure and to perforate the vein wall, and in the latter case one favours coagulation and thrombosis.

With regard to the solution great care should be taken that it be perfectly clear and free from undissolved particles. This is of much greater importance than is the use of saline or of distilled water. Those who aim at accuracy should avoid both; the former is hypertonic, the latter hypotonic. In order to obtain isotony one should use 0·6 per cent. saline solution, as has been shown by Marschalko and others.

The question of neutralisation deserves some attention, because markedly alkaline solutions favour thrombosis, as was first pointed out by Darier and Cottenot,[3] and because the acid solutions which enjoy the support of Duhot and of Spiethoff[4] tend to produce an intense general reaction, as I have been able to observe repeatedly. It is on the whole best to neutralise carefully. Any error should be on the acid side.

The general reaction following upon an intravenous injection comes on rapidly, and in nearly all cases passes off in less than 24 hours. Sometimes the disturbances are insignificant; occasionally they are alarming. They have always been a sore point, and it is edifying to note the various explanations given. Thus Heubner[5] holds the sodium-ion of the saline responsible for the rise of temperature, whilst Stopford-Taylor and Mackenna[6] find the reaction proportionate to the acuteness of the disease. This latter view, which is shared by many, implies the liberation of toxins owing to the destruction of the spirochætæ, and attributes to them all the bad effects observed. Last summer Wechselmann[7] announced that he was able to avoid nearly all ill-effects by the use of re-distilled distilled water, thus holding the dead bacteria in the commercial distilled water responsible. Of late, even the "neuro-recidive" have been put down to this "water error"—a rather surprising suggestion, as one is supposed to hold this to be of a syphilitic nature. For practical purposes it is well to carry out all possible precautions, such as starvation previous to the injection, and the use of re-distilled water. One should, however, not forget that with all possible care one only succeeds in avoiding *nearly* all bad effects.

From my point of view, the systematic disturbances are merely the reaction against the sudden introduction of an arsenical compound; that bacterial toxins may change a portion of the drug into a more toxic form of arsenic, and thus increase the intensity of the reaction, is not improbable.

The most important immediate drawbacks of the intravenous method are collapse and thrombosis. The former occurred in two of the cases injected by me. Both patients had throat lesions, and complained of a choking sensation during the injection, collapsing at the end. Both were soon restored by hypodermic injections of ether. Thrombosis can be limited by rigorous asepsis, care in the making up of the solution, &c. But it seems to be impossible to exclude it completely, as it depends upon factors beyond our control to a certain extent. Fortunately, however, it is not common and seldom of gravity when it occurs. In serious cases the entire venous channel above the puncture may become thrombosed up to the heart; and death from pulmonary embolism has been observed.

To resume: the ill-effects of the intravenous method are in the vast majority of cases unlikely to have any serious effect upon the patients. The short duration of the reaction and the absence of pain are its great advantages. Where the circulation is impaired I would advocate the use of the intramuscular method if the administration of salvarsan is deemed imperative.

Dosage.

The question of dosage is still one of the most obscure problems of the new therapy, and it will certainly require many further studies before any definite rules can be laid down. At the present time there is no unanimity on this point. Everybody who has had sufficient experience with salvarsan has had to record recurrences and accidents, and has thus been led to alter his original mode of procedure. Tentative trials to improve the results have been made by increasing the number of injections, by altering the dose per injection, and by combining salvarsan with other forms of treatment, chiefly with mercury. Thus, some claim to be able to effect a complete cure by means of two intravenous injections, whilst others require three for the same purpose. Some repeat their injections after a few days' interval, fearing the production of arseno-resistant spirochætæ; whilst others allow weeks to elapse in the hope that all the arsenic will have been eliminated by the time they administer the next injection. Iversen's example of giving an intravenous injection, followed a few days later by an intramuscular one, has found imitators who thus initiate their patients into all the unpleasant effects which salvarsan is capable of, without being able to give them an adequate compensation. Krohmeyer recommends his "chronic salvarsan treatment of syphilis" for which he uses doses of 0·1 gramme, to be repeated every three days or so, until 18 injections have been given.[8] Others favour a combination treatment of salvarsan and mercury. Personally, I started with 0·4 gramme for intragluteal injections, and gradually increased the dose up to 0·8 without being able to note better results. For intravenous injections I have used 0·4 and 0·5 in the majority of cases. Some patients received two or more injections, sometimes within short intervals, sometimes after four weeks or more. Others, again, were given mercury as well—a procedure which I consider infinitely superior to pure salvarsan treatment. I am not impressed with the necessity of large doses, because they are not capable of producing better results than medium ones. This has also been the experience of other large cliniques, such as those of Professor Rille in Leipsic, and of Professor Klingmueller in Kiel. The danger of arsenicism, on the other hand, becomes greater with the large doses, and this should not be lost sight of, despite the relatively low toxicity of the drug. To my mind the views of Milian deserve careful consideration. This author holds that 0·3–0·4 gramme is sufficient, and advises to repeat the injections frequently; examination of the individual susceptibility to arsenic is also recommended by him, and can be carried out by a subcutaneous injection of an arsenical compound. My own experience has shown me that this tolerance is rather variable; thus, I have met with violent reactions in cases where I did not expect them,

whilst some patients about whom I was somewhat anxious have reacted very slightly.

The general condition, the nature of the lesions, and the susceptibility to arsenic should be, in my opinion, the chief guides as to dosage and general plan of treatment. The proposal to regulate the dose according to the body weight has nothing in its favour except its simplicity.

Organotropism.

It is unnecessary to dwell upon the spirochætocidal effect of salvarsan which has been so carefully studied experimentally, and which is incontestable. Equally important, however, is its organotropism which was so much dreaded in the beginning, and not without reason, after the experiences with atoxyl and its substitutes. Fortunately, these fears have not been justified; as a matter of fact, salvarsan has shown itself to present this great advantage over all other arsenical compounds—that it combines an unrivalled therapeutic activity with a remarkably small toxicity. But this does by no means imply that the organotropic properties of arsenic are wanting. Like other arsenical bodies it is eliminated slowly. Thus it has been found eight months after intramuscular injections, and even in intravenous cases, which begin to eliminate the drug almost immediately, after four months. The chief storage seems to take place in the liver.

The effect upon the nutrition in general is that of a stimulant and tonic. Thus, many of our cases declared themselves to be stronger, and an increase in weight, often considerable, was usually noted. The blood is also influenced favourably; at first it undergoes a certain diminution of the red corpuscles, and this is not surprising when one considers the fragility of these cells in certain stages of the disease (Gaucher), but later a marked increase takes place (as much as from 1,000,000 to 2,000,000 per c.mm., Bezais, Klausner). Further proof of increased cell activity is the behaviour of mucous surfaces; thus, non-syphilitic lesions of mucous passages frequently heal under the influence of salvarsan.[9]

The cutaneous effects consist in drug rashes which are mostly erythematous or urticarial in character. Herpes zoster occurred in one case I had injected. Amongst the secretory troubles, œdema of the face, especially of the lips, was noted in several cases. It comes on rapidly and passes off after a short time. Instructive from this point of view is an observation by Fisichella.[10] A woman whom he had treated with salvarsan developed erythematous patches. Later she was treated by another medical man with Fowler's solution, and an identical rash supervened.

The effect upon the alimentary canal shows itself in intense thirst, vomiting, and diarrhœa. Experimentally, this has been studied by Aladow.[11] For practical purposes these troubles are an argument against large doses. The vomiting and the diarrhœa which large doses tend to produce, lead to a speedy elimination of a portion of the drug, and thus the effective dose may become a small one which could have been administered with less discomfort.

As respiratory and circulatory responses we find oppression, dyspnœa, irregularity and smallness of pulse, cyanosis, peripheral algidity, and collapse. With regard to the urinary tract, transient albuminuria, anuria, and even acute nephritis (Gaucher, Weiler), have been observed. One of the cases at Dean-street developed an intense jaundice, which terminated fatally.

The ill-effects are absolutely analogous to those observed in poisoning with other arsenical compounds, and it requires a good deal of blind infatuation not to see this. How uneasy the enthusiasts are about these bad effects is evident by their "explanations," which are replaced by new ones every few months, and are becoming so hypothetical that even such warm supporters of the remedy as Milian are unable to accept them.[12]

In practice, the organotropic properties described above are of less importance, because most syphilitics are sufficiently vigorous to cope with them. More serious is the effect upon the nervous system, which may be differentiated into a meningotropism and a neurotropism (Sicard). In its mild form this action upon the nervous system shows itself in the form of headaches, vertigo, and buzzing in the ears.[13] These symptoms, Sicard's "neurotropisme d'alarme," are a warning not to submit the patient to another injection, or to reduce at any rate the dose, if one wishes to persevere.

Meningotropism in its graver form is characterised by epileptiform convulsions, which are followed by coma, and even death. It has now been observed by a considerable number of clinicians, such as Gilbert, whose case recovered, Almquist, Kannegiesser, Fischer, Oltramare, Caraven, Gaucher, and others. They are inexplicable except as cases of acute arsenical poisoning. Post mortem, the condition of the brain and of the pia mater is diagnosed as acute hemorrhagic encephalitis.

The neurotropism shows itself most frequently in palsies of the seventh and eighth cranial nerves, as was first pointed out by Finger. This predilection of salvarsan is as obscure as that of atoxyl for the optic, or of lead for the musculo-spiral. In the opinion of Ehrlich and of his followers these paralyses are of a syphilitic origin, and supervene in cases which have been incompletely sterilised, whilst Finger regards them as purely toxic. They are by no means rare and do not require special local conditions for their production. They have been observed not only in Vienna but everywhere where salvarsan has been used extensively. They, however, often escape notice, and those who are satisfied with injecting patients and then lose sight of them do not come across them. Moreover, the patients usually consult somebody else after the disaster. I have personal knowledge of two cases which are typical in their way.

CASE 1.—A man suffering from a chancre and a macular rash received an injection of salvarsan at the London Lock Hospital. Eight days later his symptoms had completely disappeared. Believing himself cured, he underwent no further treatment. Nine weeks after the injection, suddenly deafness and facial paralysis supervened. He now sought treatment at a general hospital. As his history pointed to syphilis, a course of inunctions was instituted, with the result that the nerve lesions disappeared.

CASE 2.—A man whose syphilis had been latent for years, and who had been properly treated, was advised to undergo salvarsan treatment with the view of completely eradicating the disease. He is now suffering from facial paralysis which so far has not yielded to the various measures tried.

The former case corresponds well with the views of Ehrlich, but the latter can hardly be understood unless one admits a toxic influence of the drug upon the nerve. I believe with Rille, Delbanco, Meirowsky, and others, that both causes are at work in most cases. Primarily, the nerve is irritated and injured by the salvarsan; the syphilitic process which is so fond of locating itself upon trauma may then supervene, either immediately if there are spirochætæ in the neighbourhood, or at a later period if they have to migrate from distant foci. Thus the four groups of paralyses observed find their explanation. 1. Slight transient palsies which require no treatment. 2. Immediate paralysis curable by antisyphilitic treatment. 3. Irremediable gradual paralysis. 4. Late syphilitic palsy, amenable to antisyphilitic medication. The amount of damage done and its reparability is merely a question of degree, and depends upon the intensity of the lesion produced by the salvarsan.

Recurrences.

The recurrences after treatment with salvarsan are peculiar inasmuch as they do not correspond to the lesions which the stage of the disease would lead one to expect. In the cases treated at the London Lock Hospital they were mostly of an ulcerative character, and usually single. Thus, a man would return with a recrudescence at the site of the chancre, or with a deep ulcer in one of his tonsils, &c. These lesions, which were sometimes rather tenacious, had almost invariably the character of late, chiefly tertiary lesions (rupia, gummata, &c.). Local recurrences were the rule, but lesions in fresh places were also noted. Especially the lower limbs seem to be a situation favoured by these fresh lesions. On the whole, salvarsan tends to precipitate the course of the disease, a phenomenon which is also observable after the use of the strongest mercurial preparations, although perhaps to a lesser degree. I think one is justified in regarding this as evidence that a high degree of sterilisation has taken place. Whether this anticipation of later stages could hasten the appearance of tabes and general paralysis is impossible to say at present. It does not seem probable, however, if one admits that special factors are at work in the production of parasyphilis.

Effects upon Syphilitic Lesions.

Amongst the cases treated at the Lock Hospital with salvarsan there were a few refractory ones, but in the

[9] Semaine Médicale, 1911, No. 10.

[12] Milian, Nov. 24th, 1911, at the Société Médicale des Hôpitaux.
[13] Sicard, Société Médicale des Hôpitaux, Oct. 27th, 1911.

majority the great symptomatic effect of the new drug was evident. Therapeutic marvels, such as regeneration of bone or disappearance of parasyphilitic lesions, were not observed. In early primary cases (chancre only and negative Wassermann's reaction) the results were excellent. Considering the possibility of aborting the disease at this stage, immediate active treatment is indicated. The past has shown that by excision of the chancre and immediate vigorous mercurial treatment (Erich Hofmann, Bering, and others) an eradication of the disease is possible. In the case of salvarsan even one injection may suffice. It is therefore to be recommended at this stage. Should the attempt fail, a mitigation of the infection is almost certain. In later cases the results are less favourable. There is little hope of eradicating the disease rapidly, and the chancre often heals slowly or recurs. Where the chancre is at all extensive energetic general and local mercurial treatment produces a better result, as I have been able to observe repeatedly. In these cases I combine salvarsan with local and general mercurial treatment.

This form of therapy also seems to be the best for florid secondary syphilis. Whilst lesions of mucous surfaces (condylomata, plaques, &c.) yield rapidly to salvarsan as a rule, the cutaneous manifestations disappear slowly. This is especially the case with papules, which do better under mercurial injections. Moreover, I have gained the impression that salvarsan favours pigmentation in this type of lesion. Under combined treatment splendid results are obtainable; it would seem that the arsenic favoured the action of the mercury. One should also bear in mind that the nerve-lesions occur chiefly in cases belonging to this stage of the malady. It seems, therefore, rational to give mercury the preference in these cases.

The favourable results obtained by many in tertiary syphilis are corroborated by my observations. In this particular stage salvarsan is especially useful. Two groups of cases may be distinguished. To the former belong those whose illness has been mild and who have neglected their treatment. Only when definite lesions trouble them these opportunists seek advice, and any antisyphilitic medication is usually sufficient to remove their worry. Salvarsan, however, not only removes their lesions with greater rapidity, but also prolongs the period of subsequent latency to an extent which is not achievable by other means.

The second group—which corresponds to the malignant cases described by some—comprises those who have been treated fairly regularly, but who, nevertheless, have undergone a thorough syphilisation. Many of them are constantly threatened with fresh outbreaks, and even the most active ordinary therapy can hardly keep their disease in check. Lesions supervene regularly upon the slightest interruption of treatment, or even whilst treatment is being followed. For these cases salvarsan is a true relief: the ulcers heal, the general health improves, and the constant anxiety is removed. These grave cases are, however, very prone to relapse, and the recurrences after salvarsan tend to be more extensive and more refractory than the previous lesions, and thus I have found combined treatment most useful for them. Such therapy should be continued for a considerable time.

Firm scars, advanced infiltrative lesions of long standing, lesions which are no longer syphilitic in a strict sense, show practically no improvement; keloids were, however, favourably influenced in one case. In tertiary lingual lesions the results obtained corresponded with those which we observe after calomel injections. Most cases showed improvement, but in cases where the former injections had failed, salvarsan was equally ineffective.

Since the introduction of Wassermann's reaction late latent syphilis has received great attention. Formerly the history of the illness and the nature of the treatment were the indications, or contra-indications, for further therapeutic measures. Nowadays great importance is attached to the result of the serological test, and many regard a positive reaction as an absolute indication for further treatment. Not only is the correctness of this procedure questionable theoretically, but it is also disappointing in practice. The older the syphilis, the more difficult it becomes to influence the reaction permanently, and salvarsan shows no special superiority in this respect.

The meaning of the term "malignant syphilis" varies with different authors, and this is chiefly the reason why so many cases labeled "malignant" have been recorded since the introduction of salvarsan, and why such favourable results have been reported. Patients who progressed but little under the treatment employed, patients who showed many recurrences, patients with lesions at vital spots, &c., all figure in these reports as malignant. As these cases are examples of ordinary syphilis in which the infection is unusually severe, they are best classed in the stages to which they belong. I reserve the term "malignant syphilis" here for that peculiar form of the disease which was first described by Bazin, and which is frequently termed "syphilis maligne précoce" nowadays. Its course is atypical: the chancre is deeply ulcerative, and leads to considerable destruction of tissue (loss of glans, of entire penis, &c.; secondary manifestations are absent; within a few months cachexia and lesions of the gravest character supervene, such as perforation of palate, deep ulcerations of the skin, gummata in the viscera. This truly malignant syphilis is rare nowadays in Europe. I have been able to observe a few cases of this nature. Two of them were treated with salvarsan, and both patients died, the only deaths recorded at the London Lock Hospital during a year. The former survived his injection by nine weeks; his lesions showed no improvement whatsoever, but progressed, and fresh ones developed. The second one succumbed to an acute arsenical intoxication, and is of special interest. In August, 1909, a chancre was acquired, and subsequently was treated at a general hospital, during which period no secondary symptoms were observed. At the end of October the patient came to the hospital cachectic, covered with extensive and deep ulcers on both legs, and suffering from severe ulceration of his throat. After nine months his lesions had not quite healed, but he was much improved, and had gained a stone in weight. A course of calomel injections during July and August, 1910, removed all remaining symptoms. In September he was well and was lost sight of till February, 1911. He then returned extremely ill, barely able to speak, with terrible ulcerations about the lips and cheeks. He was given an intravenous injection of salvarsan (0·5 gramme). The reaction was intense. Two days later jaundice supervened, which became more pronounced daily. After a week death took place. A post-mortem examination was, unfortunately, not granted.

If I have in the above account paid considerable attention to the ill-effects of salvarsan it is because their appreciation is essential for the building-up of a rational therapy and not because I wish to belittle the value of this remedy. Syphilis is usually a mild disease with an exceedingly low mortality[14] and the mercurial treatment has proved itself to be efficacious and safe for many generations. It is therefore inadmissible to expose the patients to greater risks unless one can promise them an adequate compensation. A rapid cure would be the most valuable gain, and it is to be regretted that disappointment should exist in this respect. Ehrlich already recommends to extend the period of observation to a year or two years,[15] and it is not impossible that the future will impose a further extension. Broquin (Gaucher, Académie de Médecine, Nov. 21st, 1911) and others have observed cases which have spread the disease after having been "cured" by means of salvarsan, not only in their own belief, but also in the opinion of their medical advisers.

It therefore cannot be of general interest to use this new remedy exclusively. The problem of applying the various antisyphilitic drugs to the best advantage of the patients finds its solution in a combined salvarsan and mercury treatment, as advocated by Neisser, and carried out by many at present. Its superiority has been established by the experiences of large cliniques, and by serological researches (Borelli and Messineo, and others). Of course, salvarsan must have a large share in the treatment, and under certain conditions becomes the remedy of selection.

The following maxims I have found useful in planning out a treatment: 1. Salvarsan is of special value where rapidity of action or concentration of treatment is desirable—e.g., for the removal of certain infective lesions, for patients whose conditions of life render a regular treatment impossible.

[14] The statistics of the United States Census Bureau for the Registration Area with 51,000,000 inhabitants (56 per cent. of the total population) show 2999 deaths due to venereal disease, and of these 1582 are hereditary syphilitic infants under one year. There have thus been less than 1417 deaths due to acquired syphilis, whilst tuberculosis carried off 81,720, cancer 37,562, and pneumonia 70,033 persons during the same period.

[15] Münchener Medicinische Wochenschrift, 1911, No. 47.

2. It is widely applicable, as its toxicity is small. Cardiac disease, syphilis of the nervous system, and concomitant grave maladies are its chief contra-indications. 3. The intravenous method is the only recommendable one. 4. Repeated medium doses are preferable to a few large ones. 5. Its use is indicated where mercury has failed. 6. In very early cases an attempt at aborting the disease by excising the chancre and administering salvarsan is advisable. 7. In florid secondary syphilis combined salvarsan and mercury treatment should be instituted and persevered with. 8. The severe tertiary cases should also be submitted to this combined treatment. 9. In mild tertiary cases salvarsan recommends itself by the rapidity of the removal of the lesions, and by the long duration of the subsequent latency. 10. Truly malignant cases are as hopeless under salvarsan treatment as otherwise. 11. In late latent cases and in parasyphilis the administration of salvarsan presents no utility.

My sincere thanks are due to Mr. Ernest Lane for the liberal way in which he allowed me to make use of his large clinical material.

SYPHILITIC AORTITIS WITH VALVULAR INCOMPETENCY.[1]

BY ALEXANDER MORISON, M.D. EDIN., F.R.C.P. EDIN. & LOND.,
SENIOR PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

THE object with which the living patient (if one may for convenience use that unnecessary qualification) is presented, is, to illustrate some points which serve to distinguish the type of aortic valvular disease he represents from that of which the deceased patient was a pronounced example.

CASE 1. *Aortic valvular disease from rheumatic endocarditis.*—The patient is a man, 22 years of age, who has been under my observation at the Great Northern Central Hospital since he was a boy of 13. At a still earlier age he had suffered from rheumatic fever, and when he first came to hospital he had the usual clinical signs of aortic regurgitant disease with consecutive hypertrophy. When 19, incapacitated for all work and suffering much from anginoid pain, a præcordial thoracostomy was performed upon him for me by Mr. Ewen C. Stabb, with great relief to his symptoms. An account of the case was published in THE LANCET of July 4th, 1908. He was also shown at the Polyclinic among other patients about two years ago, and it may interest you to examine him again, being as he is in comparative comfort and earning his livelihood by a light occupation.

My chief reason, however, for showing him now is that he was the most typical case of aortic valvular disease from rheumatic endocarditis which I could at the moment produce in order to indicate the differences between cases of this kind and those of specific aortitis with aortic valvular incompetency, of which I purpose speaking presently. He also illustrates instructively the importance of the purely mechanical factor in heart disease.

We have here the case of a young man giving an early history of rheumatic fever, followed by aortic valvular disease, and the gradual increase of the heart in ventricular bulk and power, to conduct the blood-flow, rendered more difficult by the mechanical valvular lesion. This stage is followed by one in which a powerful ventricle is caged and limited in its effective output of energy by skeletal embarrassment, and exhausted by the effort of raising the resistant chest wall, in addition to driving the blood. Relieved by operation from this additional work, and having now to deal chiefly with the difficulty due to valvular defect, the hypertrophied organ accomplishes its task with comparative ease and with greatly lessened discomfort to the patient.

CASE 2. *Syphilitic aortitis with valvular incompetency.*—The other case, represented here only by his heart, was that of a man, 37 years of age, who was admitted under my care at the Great Northern Central Hospital on May 6th, 1911. More recently he had been man-servant to a gentleman, by whom in illness he had been treated with much consideration. He had formerly been a soldier and served in the Boer War. After his return from that campaign he stated that he had suffered from rheumatism, but had never had rheumatic fever. His general health, he maintained, had always been excellent, and he denied having ever had syphilis. This history, as I shall show, was incorrect on a material point.

In November, 1910, he began to suffer from shortness of breath and was placed in a nursing home in December and the following January. Since that time, and until his admission to the Great Northern Central Hospital, he had done little work. Exertion was stated to induce epigastric pain.

When admitted he was seen to be a well-developed man suffering little when at rest. There was no œdema, dyspnœa, or pain. The organs generally were sound except the heart; with this, the apex beat was visible in the sixth intercostal space, 2 inches to the left of the nipple line. The right limit of cardiac dulness was half an inch to the right of the sternum and the upper limit in the second intercostal space. There was a disastolic bruit audible in a curved line, with the convexity to the left, from the right cardiac base to the apex, and a systolic bruit is noted in the record as audible at the apex itself. The aortic diastolic bruit was, however, the chief sign of valvular defect. The pulse-rate was 90 and the rhythm regular. The temperature was normal.

Until the beginning of June he was apparently benefited by rest and general treatment. The note on June 1st is that the heart's apex beat was an inch and a half to the left of the nipple line, its action quite regular, the pulse-rate 88, and the diastolic bruit rather less distinct, but still loud. The patient expressed himself as feeling much better.

After this, however, his condition became less satisfactory. He lost strength, and anasarca showed itself and steadily increased. From June 15th to July 7th, as cardiac failure was progressive, digitalis in considerable doses was administered. The patient took from 15 to 20 minims of the tincture every four to six hours, but without effect upon the rate or rhythm of the pulse. It was now thought desirable, although syphilitic infection was positively denied, to determine the point by Wassermann's test, which was first employed by the pathologist to the hospital (Mr. Ernest Shaw) on July 6th, when it was found to be positive on this and six subsequent occasions. The result was so typical that the patient's blood was used as a standard in examining other cases of suspected syphilis in the hospital. Specific treatment was used, but with negative result, which was to be anticipated under the circumstances.

On July 26th the patient suddenly became a good deal worse. He had a sudden attack of pain in the præcordia with dyspnœa and extreme pallor. He had, in short, an attack of angina pectoris—the only attack while in hospital—and required vigorous stimulation to recover. Next day he was somewhat better. On July 28th cardiac arrhythmia was observed for the first time. It was of a regular type, although the ventricular pause occurred at the end of series of seven and ten pulsations. The heart-rate was 114 to 120. The arrhythmia did not persist, and at no time was there any ventricular retardation. He gradually sank, showing progressive enfeeblement of pulse, and died on August 2nd.

In view of the anatomical changes found post mortem the following further particulars of the temperature and heart's action may be given. The temperature was normal or slightly subnormal during the first five weeks after admission, with the exception of one day, when it only reached 99·6° F. During this period the pulse-rate ranged from 82 to 100, and only on one occasion reached the latter figure. In the sixth week the temperature reached 100°, when the pulse also on one occasion was 100. The seventh and eighth weeks were uneventful in this respect, the temperature and pulse-rate being as before. In the ninth week the evening temperature was slightly raised, but the highest recorded was 99·6°, and the pulse ranged from 90 to 104. The tenth week began with a subnormal temperature and ended with a slight rise above normal, which then fell for three days to subnormal, but rose on July 25th to 100°, the pulse becoming quicker and feebler and the respiration accelerated. In the lethal exitus, which lasted from July 27th to August 2nd, the temperature reached its highest point (from 100° to 100·8°), the pulse-rate rising from 114 to 132 and the respiration from 30 to 40. On two

days between these dates the temperature fell to subnormal and the pulse-rate and respiration fell with it.

Necropsy.—At the post-mortem examination—which was made by the pathologist to the hospital—a little fluid was found in both pleuræ. The lungs were congested, dry, and tough. There were several hæmorrhagic infarcts visible under the pleuræ, and one of them was decolourised and softened and had evidently existed for some days. The pericardium contained a little clear fluid; there was a large milk spot on the anterior surface of the heart and a few petechiæ behind. From the right auricular blood the bacillus coli communis was grown.

The heart itself weighed, with contained blood, 38 oz., and without it 25 oz. The organ was firm and heavy, and the muscle rather paler than normal. The dextral valves were normal. The left ventricle was much dilated, and the mitral orifice admitted three fingers and was six inches in circumference. The cusps were rather thickened and narrow. The left auricle was large. The coronary arteries opened higher up in the aorta than usual, and were small both at their orifices and in calibre.

The aorta was extremely atheromatous and rather dilated, and showed two small bulgings just above the valves. The surface of the vessel was much puckered, as the photograph (Fig. 1) shows, and there were no calcareous patches. The valves were distorted and incompetent. The left pneumogastric nerve as it approached the heart was markedly thickened. The abdominal organs showed no other change than resulted from a passive congestion.

Microscopical examination.—I later examined portions of the heart and aorta microscopically, with the following results:—

The arteries, chiefly in the auricles and interauricular septum, in the pars membranacea septi, and in the peri-aortic cellular tissue, showed advanced obliterative endarteritis. In one section a large artery and its branches, immediately above the auriculo-ventricular bundle, were completely obliterated and showed advanced connective tissue production and total disappearance of all muscular elements. The auriculo-ventricular bundle was likewise shot with an excess of veins.

While the ventricular muscle showed here and there marked fibrosis the auricular muscle and interauricular septum were most affected by fibrotic changes with interstitial nucleolysis. The first portion of the auriculo-ventricular bundle, before definite bifurcation (Fig. 2), shows advanced sclerosis with nucleolysis, and especially in its *right* half. The muscular element itself is exsanguinated and atrophied in parts. After the bundle has definitely bifurcated, in the neighbourhood of the completely obliterated large artery above referred to (Fig. 3), the same atrophic condition of muscle is observable, but most so in the *left* ventricular limb of the bundle. Ganglionic nerve cells, lying between vessels largely obliterated, show atrophy of the cell elements (Fig. 4), and in other parts nerve bundles exhibit a hyper-nucleolysis. The thickened pneumogastric nerve shows well-marked gummatous nucleolytic deposits in its fibrous sheath.

Gumma may, of course, also occur in the musculo-fibrous coat of the aorta, as is shown in Fig. 5, taken from another case of syphilitic aortitis, which died from rupture of an abdominal aneurysm. The sino-auricular ganglia were missed in the case I have related at length, in an endeavour to procure a horizontal section, but I have found some cells of the ganglia to be atrophic in another case of cardiac syphilis, without any disorder of cardiac rhythm resulting.

Remarks.—Syphilitic disease of the heart and aorta, apart from aneurysm, has, since Ricord's day, been studied by many authors. In THE LANCET in 1897[2] there is an excellent article on syphilis of the myocardium by Dr. Sidney Phillips, who refers to previous work on the subject. Sir William Osler and Dr. Mitchell Bruce dealt with the matter in their Lumleian lectures,[3] and Sir Clifford Allbutt has, by publications extending over a lengthened period, made the "suprasigmoid portion" of the aorta his own.[4] Foreign medical literature also deals with the condition fully.

These facts notwithstanding, syphilitic aortitis with valvular incompetency, though a distinct clinical entity, is a type of valvular disease which is not always recognised as such, although, with reasonably careful investigation and reflection, it should not fail to be detected. A comparison of the two cases to which I have referred above serves to indicate the chief elements in clinical diagnosis. Of the rheumatic type I have already spoken.

The patient affected with specific aortic valvular disease is usually a man, and generally comparatively young, but not a youth. His age varies from 30 or 35 to about 50. Even on careful investigation, and as a rule, no history of rheumatic or scarlet fever is to be elicited. Nor is there a history of physical disability in earlier life. The patient has usually followed some active calling, and often that of a soldier or sailor. Ultimately he becomes dyspnœic on exertion, frequently complains of attacks of pain in his chest or epigastrium, and on examination reveals aortic valvular disease with consecutive enlargement of the organ.

If he fail to respond to treatment (as he frequently does at the stage at which he presents himself) and die, the necropsy reveals an atheromatous aorta and puckering of the valves, which, considering the comparative youth of the patient in most cases, and an absence of the history of the usual acute infections which induce heart disease, leads, even when syphilitic infection is denied, to a diagnosis of the consequences of that condition. More minute investigation of the textures confirms the correctness of this view.

The clinical history and anatomical examination of the case I have related exemplify these facts in a typical manner. The case is also interesting because, although there were well-marked changes in the auriculo-ventricular bundle, such as have been described as occurring in cases exhibiting "heart-block" or the dissociated action of the auricles and ventricles, that condition was not present in this instance. Had it occurred partially or completely, the anatomical conditions found would have been considered by some quite sufficient to account for that state.

Dr. Thomas Lewis has collected and carefully analysed 50 cases of complete or partial heart-block, in 11 of which syphilitic invasion or affection of the auriculo-ventricular bundle was regarded as causal of that condition.[5]

The anatomical changes, whether in nerve, muscle, or interstitial tissue, appear to be largely due in cardiac syphilis to that condition of the blood-vessels so characteristic of this state, which interferes with the due nutrition of the structures affected. The pulmonary infarction and bacillary heart blood of the case I have related was evidently a so-called terminal infection and had no bearing on the general clinical history.

Treatment.—As Sir William Osler has remarked with regard to the treatment of aortic aneurysm of specific origin, it is its prevention by suitable and sufficient treatment of the early infection which is most important. This doubtless holds good also for other ultimate manifestations of cardio-vascular syphilis. But to prevent is not to treat either aneurysm or aortitis. The frequently observed beneficial effects of the treatment of late manifestations of syphilis by mercury and the iodides justify, nevertheless, the expectation of benefit from this line of treatment in the type of case with which we have been dealing. But when cardiac failure has occurred in an advanced case such as I have related, little good can be expected to follow the use of any remedy, the anatomical changes described being permanent and important structures atrophied and impaired in function.

Although common experience teaches us that cardiac failure with a mitral lesion is more amenable to treatment by the digitalis group than a similar failure with aortic lesion, we know that digitalis has at times a well-marked effect in reducing the heart-rate in aortic valvular disease. The failure of these agents to do so in the case discussed has a certain interest, as it has been suggested that lesions of the bundle of His render the retardant action of the digitalis group on ventricular action more probable. Such a *modus operandi* of these agents is, however, at present, merely a supposition on the part of those who entertain it.

THE CLINICAL SIGNIFICANCE OF X RAY AND RADIUM MEASUREMENTS.[1]

BY S. RUSS, D.Sc.,
BEIT MEMORIAL RESEARCH FELLOW.

(*From the Cancer Research Laboratories, Middlesex Hospital.*)

IT is desirable for clinical and experimental biological purposes to have some comparative measurements between the intensity and character of the radiation from an X ray bulb working under specified conditions and that from a known quantity of radium. The character of the radiation from both is complex. Under whatever conditions an X ray bulb is working the radiation coming away from it is heterogeneous, consisting of rays varying in their penetrating power. The radiation from radium (and the short-lived products in equilibrium with it, Ra emanation RaA, RaB, and RaC) consists of alpha, beta, and gamma rays, which are also heterogeneous in type.

Measurements have been made of the penetrability through

[1] A paper read before the Roentgen Society on Jan. 2nd, 1912.

aluminium of the X rays emitted by a bulb under varying conditions of spark gap, and compared with the penetrating power of beta and gamma rays through the same substance. The alpha rays from radium are completely stopped by 0·05 mm. aluminium, so that under most conditions of irradiation their effects may be neglected.

The intensity of X rays has been measured by the ionisation that they produce in the air of an electroscope. This has been compared with the ionisation produced in the same electroscope by the gamma rays from a known quantity of radium.

The last part of the paper affords some evidence that the biological effects of X, beta and gamma rays are proportional to the ionising action of these rays.

Method of Measurement.

The character of the X rays from a bulb under varying conditions of spark gap was determined by means of the

FIG. 1.

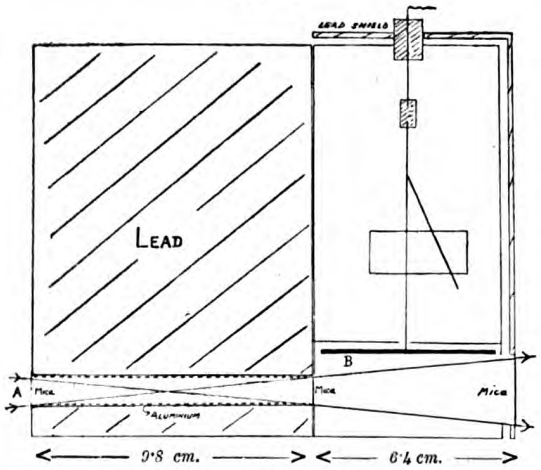

Diagram of apparatus.

apparatus in Fig. 1. A beam of X rays enters the electroscope through an aperture A in a lead block which was lined with aluminium to eliminate any secondary X rays from the lead. The beam on entering the electroscope ionised the air beneath the metal plate B which was connected to a gold leaf system, the rate of fall of the gold leaf serving as a measure of the amount of ionisation produced by the rays. The mica windows allowed of the accurate alignment of the anode. By placing aluminium screens at A in the path of the beam the penetrability of the rays is found by the change in the ionisation thereby produced.

The criterion for the homogeneity of X rays is that they are absorbed according to an exponential law. Corresponding to any thickness of matter traversed by the rays the ionisation has a certain value. If the logarithms of the values of the ionisation are plotted as ordinates and the thickness of matter traversed as abscissæ, the points on the diagram will lie on a straight line if the absorption of the rays has followed an exponential law. This test when applied to the radiation from an X ray bulb reveals the heterogeneous character of the rays, as may be seen from Fig. 2. Three typical cases are exhibited, Curves I., II., and III., corresponding to spark gaps of 4·5, 8·5, and 19 cm. respectively, the same current flowing through the primary in each case. At 19 cm. spark gap the beam is almost homogeneous after 1·12 mm. of Al have been traversed, as may be seen from the approach of the curve to a straight line. On the same diagram are drawn corresponding curves for the beta and gamma rays from radium, use being made of data obtained by Kovarik and McLelland. It will be seen that whereas the beta rays are rather more easily absorbed by aluminium than the X rays excited by a very "soft" bulb, the gamma rays are very much more penetrating (about 30 times actually) than the X rays from a very "hard" bulb.

The data corresponding to the three cases considered are collected in Table I.

TABLE I.—*Absorption of X Rays by Aluminium.*

Current.		Spark gap.	—
Primary.	Secondary.		
4·5 ampères.	0·9 milliampères.	4·5 cm.	I.
,, ,,	0·45 ,,	8·5 ,,	II.
,, ,,	0·15 ,,	19 ,,	III.

Ionisation after Passing through Aluminium.

	0	0·56 mm.	1·12 mm.	1·68 mm.	2·24 mm.	2·8 mm.	3·36 mm.
I.	100	25·1	15·7	9·8	8·5	7·5	—
II.	100	34·7	23·0	15·1	12·7	10·6	9·6
III.	100	40·2	29·2	24·4	21·2	17·5	15·3

Percentage Absorbed by 0·56 mm. Al after Rays have passed through the following thicknesses:—

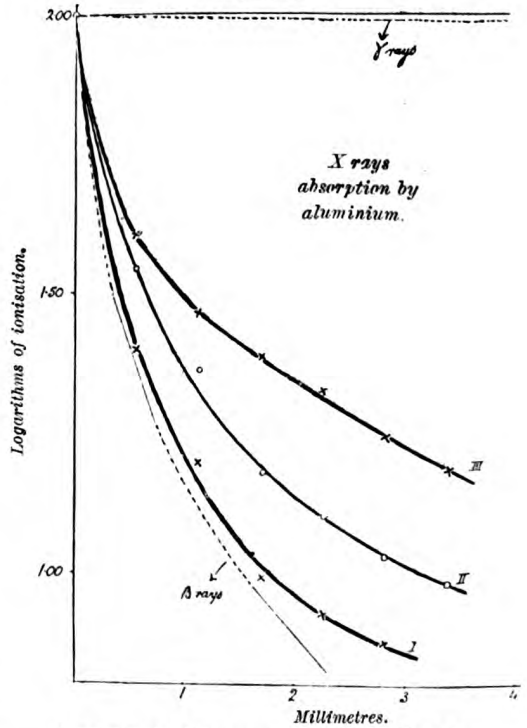
	0	0·56 mm.	1·12 mm.	1·68 mm.	2·24 mm.	2·8 mm.
I	74·9	37·4	37·6	13·2	11·2	—
II.	65·3	33·7	34·3	15·9	16·1	9·8
III.	59·8	27·2	16·4	13·1	17·4	12·5

For the whole series of observations the current through the primary coil was kept constant. If this were changed the type of radiation from the bulb would be altered.

The Coefficient of Absorption of the Rays.

It is convenient to refer to the penetrating power of a beam

FIG. 2.



Curves showing heterogeneous character of the rays.

of rays in terms of a coefficient[2] (λ) the numerical value of

[2] The value of λ is obtained as follows: The intensity of a homogeneous beam in its passage through matter may be represented by the equation—

$$I = I_0 e^{-\lambda d}.$$

Where I_0 is the initial ionisation produced by the beam and I the ionisation produced after a thickness of matter d has been traversed. Hence—

$$= \frac{2{\cdot}302\,(\log_{10} I_0 - \log_{10} I)}{d}.$$

which is inversely proportional to the penetrability of the beam. A large value of λ corresponds to an easily absorbed beam and a small value to a very penetrating one. λ also varies according to the nature of the absorbing material. If after traversing 1 cm. of matter the ionisation in the electroscope is reduced to one half its initial value, $\lambda = 0{\cdot}69$ cm.$^{-1}$. This is just about the mean value found for the absorption by fatty tissue (breast) of a beam of X rays of "medium" hardness (9·5 cm. spark gap). For a "hard" beam, previously screened by 1·12 mm. aluminium, the value of λ for the same tissue is $0{\cdot}45$ cm.$^{-1}$, and this value is used in a later section to illustrate the fall in the intensity of X rays in their passage through the tissues. It is clear that when dealing with a heterogeneous beam the value of λ varies with each succeeding layer of matter traversed, whereas it is a constant if the beam is homogeneous.

Approximate values of λ for the maximum part of the radiation corresponding to Cases I., II., and III. have been obtained after the very soft components were cut out. These are collected in Table II., which also contains values of λ for the beta and gamma rays from radium.

TABLE II.—*Values of the Coefficient of Absorption (λ in cm.$^{-1}$) for Aluminium.*

X rays under conditions of spark gap.						
Beta rays		4·5 cm.		8·5 cm.	19 cm.	Gamma rays.
75–13·5	.....	8·1	.....	5·6	..... 2·9	..... 0·104

The coefficient of absorption λ being inversely proportional to the penetration of the rays, the enormous difference in the penetrating power of beta and gamma rays is easily appreciated by a comparison of their coefficients.

The Ionisation caused by X and Gamma Rays.

The ionisations caused by unscreened X rays at a spark gap of 9 cm. and by the screened rays at a spark gap of 19 cm. were measured and compared with that produced by the gamma rays from a known quantity of radium. The results are collected in Table III., from which may be seen the quantity of radium required to give the same ionisation in the electroscope by means of gamma rays, as that produced by an X ray bulb working under the specified conditions. The ionising effect of the beta rays from radium being about 50 times that of the gamma rays, the beta ray equivalence may be taken as one-fiftieth of the numbers given for the gamma rays.

TABLE III.—*Comparison of Ionisations.*

19 ,,	1·12 mm. Al.	,,	17·3 ,,	153,000	8·88

Clinical Considerations.

1. *Surface conditions of irradiation.*—The unscreened X rays from a bulb running under a spark gap of 9 cm. are equivalent in ionising action to the gamma rays from 53·8 grm. of radium, if placed in the same position as the anode (*vide* Table III.). Experimentally the anode is not usually nearer than 10 cm. from the surface to be irradiated, whereas an application of radium may be made directly on the part in question, and therefore one half of the total radiation is utilised. Hence, comparing the intensity of irradiation per square centimetre of surface under these conditions, and taking the area of the sphere with the anode at centre as 1250 sq. cm., we have—

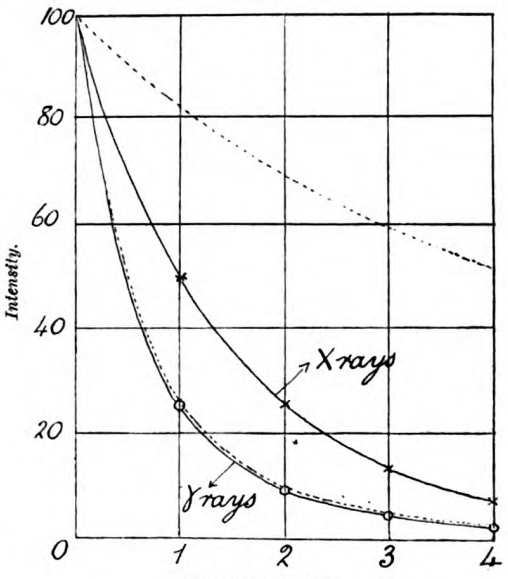
$$\text{X ray intensity per sq. cm.} = \text{gamma rays from } \frac{53{\cdot}8 \times 2}{1250} \text{ grm. radium per sq. cm.}$$
$$= \text{gamma rays from } 86{\cdot}1 \text{ mgrm. radium per sq. cm.}$$
$$= \text{gamma rays from } 146{\cdot}6 \text{ mgrm. radium bromide per sq. cm.}$$
$$= \text{beta rays from } 2{\cdot}93 \text{ mgrm. radium bromide per sq. cm.}$$

Assuming the simplest relation between the biological effects of the rays and the ionisation that they produce, it might be expected that the irradiation of thin layers of tissue by X rays from a "medium" bulb or by the beta rays from 2·93 mgrm. of radium bromide per square centimetre, for the same interval of time, would lead to similar biological results under the conditions specified above.

Some experiments have recently been completed by Dr. B. H. Wedd and myself (which were communicated to the meeting of the Pathological Society of Great Britain and Ireland on Jan. 5th, 1912) upon the effect of these different rays on inoculable mouse tumours.

With an intensity of 2·81 mgrm. of radium bromide per square centimetre the effect of the beta rays upon the tumours for various times of exposure bore a marked resemblance to the effects under "medium" X rays for a similar time range. With the above quantity of radium an exposure of the tumours for 18 hours to the gamma rays

FIG. 3.



Curves showing diminution in intensity of rays in passing through the tissues.

failed to give definite evidence of any biological effects. Subsequent calculation on the above lines indicated that an exposure lasting 50 hours would have been necessary.

2. *Deep-seated conditions of irradiation.*—Under these circumstances a "hard" bulb would be used and the soft constituents of the beam of X rays may be cut out by 1·12 mm. of aluminium. Reference to Table III. shows that for a screened bulb running at 19 cm. spark gap the anode of which is at a distance of 10 cm. from the surface in question—

$$\text{X ray intensity per sq. cm.} = \text{gamma rays from } \frac{8{\cdot}88 \times 2}{1250} \text{ grm. radium per sq. cm.}$$
$$= \text{gamma rays from } 24{\cdot}3 \text{ mgrm. radium bromide per sq. cm.}$$

This is the condition holding at the surface. The intensity of the X rays in passing through the tissue diminishes owing to the increase in distance from the anode, and to the absorption of the rays. The variation in intensity due to the increase in distance, assuming the inverse square law to hold, is shown by the upper dotted line in Fig. 3, and when the

absorption is taken into account the true diminution of intensity through successive layers of tissue is shown by the full line curve. The value for λ is taken as $0 \cdot 45$ cm.$^{-1}$ (*vide supra*).

If a disc 1 cm. in diameter be covered with radium the gamma radiation per square centimetre vertically below it decreases with the distance in the manner indicated by the lower dotted curve in Fig. 3. Taking the absorption of the rays by the tissue into account the full line curve is obtained. The rapid fall in the intensity through succesive layers is almost entirely due to the increase in distance, the absorption by the tissue being very small.

It will be seen that starting with equivalent intensities at the surface there would, under the experimental conditions cited, be a more marked diminution in the intensity of the gamma rays than in the X rays, despite the fact that the absorption of the rays by the tissues was nearly 30 times greater in the latter than in the former case. It must be understood that this quantitative estimation of the amount of radiation received by different layers of tissue is not a general one, but refers to the particular case in question. If the radium were deposited over a larger area the fall in intensity through the tissues would not be so large.

MEMBRANOUS RHINITIS:

ITS RELATION TO DIPHTHERIA AND ITS TREATMENT BY AUTOGENOUS VACCINE.

BY DUNCAN FORBES, M.D. EDIN., B.SC., D.P.H.,
MEDICAL OFFICER OF HEALTH, BRIGHTON;
AND
H. P. NEWSHOLME, M.B. OXON., M.R.C.P. LOND., B.SC.,
RESIDENT MEDICAL OFFICER, BOROUGH FEVER HOSPITAL, BRIGHTON.

THIS paper is written in the first place to illustrate the relation between membranous rhinitis and diphtheria by an account of a school outbreak in which both conditions occurred; and in the second to describe the treatment of three cases of membranous rhinitis by an autogenous vaccine. Incidentally attention will be drawn to secondary diphtheritic lesions in one of the cases.

General features.

Membranous, fibrinous, or primary diphtheritic rhinitis has been recognised as a disease since 1871, when Schuller published the first clear account of it. It is a condition occurring mainly during childhood, and characterised by the formation in the nasal fossæ of a definite membrane from which virulent diphtheria bacilli can be obtained with ease. With the membrane is frequently associated an extremely profuse and often irritating discharge which may cause excoriation of the nostrils. In the untreated condition the membrane is white, is closely incorporated with the mucous membrane, and bleeds readily on being swabbed. The patient's general health commonly is almost or quite unimpaired, the condition suggesting only a persistent severe cold in the head, and the paralytic and cardiac sequelæ of ordinary diphtheria are never found. This primary diphtheritic rhinitis is of course totally distinct from the serious secondary form occurring in naso-pharyngeal diphtheria.

Cases of the disease have been reported by Major, Seifert, Chapin, Gluck, Raulin, Gerber, Podack, Pluder, Wishart, Abel, and others. A complete bibliography of these is given by Ravenel[1] up to 1895 and by Lack[2] up to 1899, while Cartaz[3] gives a few more recent references up to 1908. Since then other cases have been reported at intervals, one of the latest being that of Ellett.[4] Of the monographs on the subject those of Lack[2] and of Gerber and Podack[5] are among the most complete and authoritative.

The identity of the organism causing membranous rhinitis with that causing diphtheria has been demonstrated repeatedly. The researches of Lack[2] and of Meyer[6] in this respect are among the most complete. In both the morphological, cultural, and animal tests were made. The organism found in membranous rhinitis is frequently of very marked virulence, and is in all cases virulent in some degree.

Frequency.

The frequency of the condition is not sufficiently recognised, a fact due doubtless in part to inadequate examination and in part to the characteristic membrane being hidden by the profuse secretion which accompanies it. Lack[2] found that as many as 2¼ per cent. of the cases seen at the throat and ear department of the Paddington Green Children's Hospital in 1897 had membranous rhinitis, while Potter[7] believes that this affection forms 2 per cent. of all cases of acute rhinitis.

Duration.

Its duration is very variable. The average is given as three weeks (Potter, quoted by Clifford Allbutt[8]), but in many instances the disease is extremely chronic. Out of 36 cases recorded by Lack the most chronic recovered in 10, 12, 14, and 18 weeks.

Relation to Diphtheria.

The relation of membranous rhinitis to diphtheria has been a much-debated point. Some observers hold the view that the two diseases are quite distinct and that one cannot give rise to the other, while in the opinion of others they are closely related, each being capable of causing the other. Lack,[2] from a careful analysis of a considerable number of cases, concludes that membranous rhinitis has a special tendency to reproduce itself and not to produce diphtheria. He admits, however, that very rarely diphtheria may give rise by direct infection to fibrinous rhinitis. Parker,[9] again, states that "membranous rhinitis is infectious as membranous rhinitis and diphtheria as diphtheria." For the second view Pluder[10] and others record cases where contacts with membranous rhinitis have developed definite diphtheria with diphtheritic exudate on the tonsils. *A priori* the fact that the bacillus is identical for the two diseases suggests strongly that the one will be capable of giving rise to the other. Of the two, membranous rhinitis would appear to give the most fruitful opportunities of infection, from the abundance of infective nasal discharge which must almost inevitably be distributed broadcast. The nose is likely to be a frequent channel of infection, from the readiness with which in young children the lips, face, fingers, clothes, handkerchief, books, &c., become contaminated with nasal secretion. The extreme importance of nasal discharge in the spread of diphtheria, and especially the importance of membranous rhinitis as a source of a discharge of virulent nature, has been emphasised by one of us[11] on a previous occasion.

We would here urge a very important practical point in the taking of swabs from cases of fibrinous rhinitis. The nasal discharge should be wiped away and the swab firmly applied directly upon the membrane. At times the nasal secretion gives negative results.

A School Outbreak of Diphtheria.

In reference to the probable influence of membranous rhinitis in the spread of diphtheria, attention is called to the following school outbreak of diphtheria.

Prior to the cases about to be described, which began during September, 1911, there had been no notified or suspected diphtheria in the school during the year. Throughout the outbreak there was very little diphtheria in Brighton as a whole. The first group of cases, occurring between Sept. 8th and Oct. 4th, was limited to Class IV. of the infants' department, and was as follows:—

1. On Sept. 8th a girl, A, developed a sore throat, but remained at school till Sept. 11th. She was then excluded for three weeks and returned to school on Oct. 2nd.

2. On Sept. 11th a girl, B, developed diphtheria, for which she was admitted to the Fever Hospital on Sept. 13th. She had then abundant exudate on both tonsils. The throat swab was positive, the nose swab negative.

3. On Sept. 12th a girl, C, stayed away from school with a sore throat and exudate on the tonsils. She was visited at home, but the throat-swab taken was found to be negative. She returned to school, after three weeks' exclusion, on Oct. 2nd.

4. On Sept. 13th a boy, D, had a sore throat. He attended school on Sept. 14th, but was then excluded for three weeks. He returned on Oct. 4th.

5. On Monday, Oct. 2nd, a girl, E, fell ill with diphtheria and was taken to the Fever Hospital on the same day. She had then exudate on one tonsil. The throat swab was positive, the nose swab negative. E's last attendance at school was on Friday, Sept. 29th.

As a result of this case following on the previous suspicious series the school was visited on Oct. 4th and swabs taken from all children in Class IV. exciting suspicion. Those children in particular were picked out who had either a history of recent sore-throat or a sore or running nose. The results of the bacteriological examination were as follows:—

1. Throat swabs from C and D were positive, from A negative, but three weeks had elapsed since the sore-throat in this case.

2. A girl, F, was found to be suffering from definite membranous rhinitis with copious nasal discharge. The nasal swab was positive.
3. A boy, G, had a positive nasal swab. This boy, who was taken to the Fever Hospital on Oct. 4th, was an ordinary chronic carrier in good general health. After suitable local treatment he was discharged free from diphtheria bacilli on Nov. 2nd.

Thus between Sept. 8th and Oct. 4th the following cases had occurred in one class of about 50 children in a school which had apparently been free from diphtheria for many months: four cases of diphtheria, one of sore-throat yielding a negative swab three weeks after onset, one nasal diphtheria carrier without obvious disease, and one case of membranous rhinitis. Between these dates no other cases of diphtheria, certain or suspected, occurred in the school.

It is unfortunately impossible to date the onset of the membranous rhinitis in F. The association, however, of membranous rhinitis and diphtheria is so close as regards time and place that it suggests strongly that the two diseases did not arise independently of one another.

A fortnight later three further cases of diphtheria occurred in the infants' department of the same school. On Oct. 14th H in Class V. developed a severe attack, while about Oct. 22nd P in Class IV. and R in Class III. had mild attacks.

As the result of an examination of school children on Oct. 24th a second group of cases, this time in Class V. of the infants' department, was isolated as follows:—

1. A boy, J, who had been absent on Oct. 20th with a sore throat gave a positive throat swab.
2. Three children, K, L, and M were found in Class V. with definite membranous rhinitis. The nose swab in each case was positive. There was no evidence of the date of onset in K, but she had at the time of the examination a sister under medical treatment at home for sore-throat. A swab taken by the doctor from this sister was negative. L had had a sore throat on Oct. 21st, and at the time of examination had profuse nasal discharge and left otorrhœa. M had had nasal discharge for some weeks before Oct. 24th.

This second group, comprising three cases of membranous rhinitis and two of diphtheria occurring in one class of about 50 children, suggests two conclusions: first, that membranous rhinitis, as maintained by Lack, is specially prone to produce a similar disease in others, as indicated by the occurrence of three cases in one class; and secondly, that either membranous rhinitis may give rise to diphtheria or else *vice versâ*. The first conclusion is somewhat strengthened by the negative evidence resulting from the examination, at about the same date, of all children in the infants' department of another school. The children were examined especially for the presence of membranous rhinitis, and no case was found, so that three cases occurring in a single class of a department may be considered as an unusually large proportion.

Bacteriological Diagnosis of Three Cases of Membranous Rhinitis Admitted to the Brighton Fever Hospital.

It may be well, before giving details of the three cases under review, to summarise their bacteriological diagnosis.

Cultures were made on blood serum and pure sub-cultures obtained on the same medium from (*a*) F's nose, (*b*) M's nose, (*c*) M's whitlow, (*d*) L's nose, (*e*) L's left ear (otorrhœa). For each of these five subcultures the following facts held good:—

1. *Cultural characters.*—(*α*) The growths on all the ordinary solid media were those characteristic of the diphtheria bacillus.

(*β*) In broth the growth was very scanty, but on subculture growth was better. The broth remained clear, and a fine deposit was formed.

(*γ*) Acid was not at first obtained with litmus glucose broth. This was due, however, to difficult growth in broth. After subculture in broth, as suggested by Graham Smith,[12] an acid reaction was readily obtained.

(*δ*) Indol (without addition of nitrite) was obtained in peptone water after incubation for a week at 37° C.

2. *Morphology and staining.*—A Gram-positive beaded bacillus of the long variety, with clubbed ends and polar staining, showing typical involution forms in 24–48 hours, and staining deeply with methylene blue.

3. *Virulence.*—The virulence was kindly tested by Dr. Arthur Eastwood, who reports that "all the five cultures are of high virulence towards guinea-pigs, death being in each case produced in from 24 to 30 hours with a loopful of culture weighing about 3½ milligrammes."

Vaccine Treatment.

Few cases are recorded of vaccine treatment in diphtheritic infections. Allen,[13] Graham Smith,[12] Lack,[14] StClair Thomson,[15] and Clifford Allbutt[3] do not mention it in discussing the treatment of membranous rhinitis; nor was the method suggested in a recent discussion[16] on nasal diphtheria at a meeting of the New York Academy of Medicine at Philadelphia.

Petruschky[17] tried autogenous vaccines of diphtheria bacilli in 6 cases of chronic diphtheritic infection of the fauces with successful results, in 4 of the cases after one or two doses, in the other 2 after repeated injections extending over many months. The vaccine used was an emulsion of the bacilli in sterile saline (1 in 100), and the doses were from 0·1 to 0·5 c.c., given subcutaneously. More recently Smith[18] had a successful result after giving two doses of an autogenous vaccine to a chronic diphtheria carrier whose fauces had been positive for 22 weeks. Here a combined diphtheria and staphylococcus vaccine was given, the first dose of diphtheria bacilli being 6,000,000 and the second 8,000,000.

Watson Williams[19] and Bosanquet and Eyre[20] mention vaccine treatment in persistent infection of the throat and nose, but do not give instances. The latter recommend doses of 5 to 10 millions at intervals of five to seven days, and state that the bacilli disappear after one or two doses. Wright[21] considers that vaccine treatment would probably be beneficial. Goodall has used triturated diphtheria bacilli with success (quoted by Hewlett[22]).

The three cases of membranous rhinitis received into the Brighton Fever Hospital each underwent a course of treatment with an autogenous vaccine of diphtheria bacilli.

Preparation of vaccine.—The patient's own organism was obtained in a pure state by successive subcultures on blood serum. The pure culture was incubated at 37° C. for 48 hours, and then emulsified in sterile normal saline. After thorough shaking the emulsion was tested against normal human blood to determine its concentration. Counting was found to be unusually difficult, as it was at times very hard to distinguish the round and irregularly globoid involution forms from blood platelets. The use of a Thoma-Zeiss pipette and slide would doubtless have given more accurate accounts. After the count the emulsion was heated to 60° C. for half an hour, and appropriate amounts withdrawn and injected into rubber-capped bottles containing 0·5 per cent. phenol.

Doses were given usually at intervals of five to seven days; but owing to unavoidable delay in making up further doses of vaccine it was at times impossible to adhere to this rule strictly. Neither general reaction nor reaction at the site of inoculation, except for occasional very slight redness, followed any one of the doses. Throughout the vaccine course all three cases had the nose syringed twice a day with a dilute alkaline solution. This was omitted for 24 hours before the taking of swabs.

CASE 1.—F, a girl, aged 5 years. Admitted Oct. 6th, 1911.

History.—No history of onset obtainable.

On admission. A rosy-cheeked girl; general health good; child in high spirits. Grey membrane lining both nasal cavities, seen only after the superficial secretion had been wiped away. The nose bled readily when a swab was taken. Nasal discharge thick, yellow, and very profuse. Tonsils enlarged and adenoids in pharynx, which showed no recent signs of inflammation. Nasal swab positive, the organism being highly virulent to guinea-pigs. Throat swab negative.

For one month plugging of nostrils with cotton-wool soaked in diphtheria antitoxin was tried, together with alkaline nasal douches. There was, however, no obvious diminution in membrane or rhinorrhœa, and both nostrils still gave an almost pure culture of diphtheria bacilli on blood serum.

Vaccine treatment.—A vaccine was prepared from a pure diphtheria culture from the nose and given as follows: Nov. 9th, 5 millions (5 m.); Nov. 15th, 10 m.; Nov. 20th, 40 m.; Nov. 27th, 80 m.; Dec. 2nd, 100 m.; Dec. 9th, 200 m.; Dec. 20th, 400 m.

The first dose had no perceptible effect. From the second dose onwards the membrane and the rhinorrhœa diminished. No membrane was seen after the third dose, and after the fifth dose the nasal discharge had almost disappeared. The nose was still positive after the third dose, but became negative after the fourth, and remained negative for 19 days, during which interval six swabs were examined carefully. For the last few days of this interval glairy mucus began to accumulate in the nose, the mucous membrane over the inferior turbinate bones looked rather red, and mucus was seen in the pharynx. At the same time, on Dec. 19th, the nasal swab again contained diphtheria bacilli in small numbers. No membrane was seen in the nose. The nose still remained positive after a further final dose of 400 millions.

This result suggests that an autogenous vaccine has a rapid action in the removal of adherent membrane and in lessening the nasal secretion which accompanies it. But since at the onset of a mild catarrh of the naso-pharynx the bacilli reappeared in small numbers in the nose and were unaffected by a further large dose of vaccine, it would seem that the

latter loses its potency when the bacilli are no longer lodged in close vascular relation with the mucous membrane, but are present chiefly in the free mucous secretion. This loss of potency is perhaps only to be expected, seeing that the chief paths by which antibodies can reach the bacilli have been largely obliterated by the disappearance of the membrane with its vascular and lymphatic connexions.

It is also possible that the diphtheria bacilli found during the catarrh were not descendants of the original inhabitants of the nose, but a fresh strain derived from some other patient in the ward. Such cases of bacterial cross infection occur occasionally in diphtheria wards. A patient who on admission has a negative nose swab may after weeks give a positive result. This may occur also in non-diphtheritic cases nursed in a diphtheria ward, in whom there is no possibility of the bacilli having spread to the nose direct from the patient's own throat. Had such infection *ab extra* happened in the patient in question it might offer another explanation of the inefficacy of the vaccine at this stage, since the vaccine would no longer be autogenous to the fresh infection. That cross-infection occurred in this case can, however, only be a surmise, and perhaps an improbable one.

CASE 2.—M, a boy aged 5 years. Admitted Oct. 24th.

History.—"Profuse running at the nose for some weeks before admission."

On admission.—An anæmic child, with large tonsils and an adenoid facies. No signs of recent inflammation in the fauces. Profuse yellowish nasal discharge, excoriating the angles of the nostrils. On wiping away this discharge definite membrane could be seen lining the outer walls of the nasal cavity. The nasal mucous membrane bled very readily on being touched. The face was dotted with small superficial sores. The throat swab was negative, the nose swab positive, giving almost a pure culture of virulent diphtheria bacilli. Two days after admission a whitlow developed which on incision gave a nearly pure culture of virulent diphtheria bacilli.

Vaccine treatment.—The organism from the whitlow was used for preparing a vaccine, as it happened to give a pure culture readily. It was judged that the whitlow was due to direct infection from the nose, since the boy was in the habit of biting his nails, and his fingers were rough and torn, giving abundant places of lodgment for infected nasal discharge.

The doses given were as follows: Nov. 3rd, 5 millions (5 m.); Nov. 9th, 10 m.; Nov. 15th, 20 m.; Nov. 27th, 50 m.; Dec. 2nd, 100 m.; Dec. 10th, 200 m.; and Dec. 21st, 400 m.

The whitlow was still discharging at the time of the first dose. On the day after the first injection pus reaccumulated in the whitlow, which, however, healed extremely quickly on removal of the nail. On the day following the third injection a second whitlow appeared on another finger, yielding, as in the first instance, diphtheria bacilli. This also healed in the course of a day or two after incision. From the second dose onwards the membrane and the rhinorrhœa diminished, until by the beginning of December the nose was almost dry, and no membrane could be seen. The nasal swab was negative after the third injection. From Nov. 18th to Dec. 16th seven consecutive nasal swabs were negative. The nose then became rather blocked again for a few days and the swab showed diphtheria bacilli in small numbers. These were not abolished by a further dose of 400 millions. No membrane could be seen at this stage.

This case suggests the same conclusions as were advanced in regard to Case 1. It also seems to indicate that an autogenous vaccine is of value in curing diphtheritic whitlows. It will be remembered that the vaccine used in this case was prepared from a whitlow.

CASE 3.—L, a boy aged 5 years. Admitted Oct. 24th.

History.—Sore-throat three days before admission.

On admission.—Child anæmic, adenoid facies very marked. Tonsils rather large, no exudate. Very profuse thick nasal discharge, hiding a thin membrane lining the outer walls of each nostril. Profuse left otorrhœa.

Diphtheria bacilli were grown from the throat swab; from the nose swab in almost pure culture; and from the ear discharge also in great profusion. Cultures from the nose and from the left ear were proved to be highly virulent to guinea-pigs.

Vaccine Treatment.—A vaccine was prepared from the nose. Doses were given as follows:—Nov. 9th, 5 millions (5 m.); Nov. 15th, 10 m.; Nov. 20th, 40 m.; Nov. 27th, 80 m.; Dec. 2nd, 100 m.; Dec. 15th, 200 m.; Dec. 21st, 400 m.

Two days after the first dose the nose became decidedly clearer and the membrane less obvious. Two days after the second dose the otorrhœa was much diminished, while the nose continued to clear. Three days after the third dose the otorrhœa ceased, and though a few diphtheria bacilli were still present in the nasal swab the nose seemed quite clean. The nose continued positive throughout, though to a slight degree, up to and after the final dose. On Dec. 12th, at which time the boy had had no dose for ten days, he had a febrile attack with right earache, followed rapidly by profuse right otorrhœa, then by nasal discharge, then by left otorrhœa. No membrane could be seen in the nose. Diphtheria bacilli in small numbers were present in the nose and in the discharge from each ear. This nasal discharge and otorrhœa seemed quite unaffected by a final large dose of 400 millions.

It should be mentioned that it was found impracticable to continue the vaccine treatment after Dec. 21st, at which time each case had received a dose of 400 millions.

The last case is of interest in showing that though the membrane and the original rhinorrhœa and otorrhœa cleared up rapidly under vaccine treatment, nevertheless the nose remained positive. But whereas the swabs before treatment gave almost pure cultures, after treatment the diphtheria bacilli were scanty, requiring for their detection careful search through several fields of a microscope. It seemed probable that the second attack of rhinorrhœa and otorrhœa was due to some other organism, and that the diphtheria bacilli found were merely casual guests rather than the cause of the condition. Since the nasal mucous membrane is apt to be unhealthy and liable to recurrent infection in membranous rhinitis, a combination of diphtheritic with autogenous staphylococcal or streptococcal vaccine from the nose might be of value towards the end of the course in preventing relapse. This would, at any rate, seem a reasonable procedure if Meyer[6] is correct in believing membranous rhinitis to be grafted on to a previous staphylococcal or streptococcal infection of the nose.

One other point needs mention. The disappearance of membrane following treatment by vaccine might conceivably be due only to the natural tendency of the disease to recovery. But the definite diminution in secretion, after one dose in one case, and after two doses in the other two, seems to indicate that the vaccine was a real factor in the improvement. One case also (F) had had one month's previous treatment without any change, and the improvement followed shortly after vaccine treatment was begun.

General Conclusions.

The facts indicated above seem to warrant the following conclusions:—

1. Membranous rhinitis can readily produce similar disease in others.

2. The connexion between membranous rhinitis and diphtheria in the school outbreak detailed above was so intimate as to make it almost certain that there was a causal relation between them.

3. It is a point of practical importance that the comparatively frequent occurrence and great infectivity of membranous rhinitis should be recognised widely. Missed cases of the disease would readily account for a not inconsiderable proportion of school diphtheria.

4. An autogenous vaccine seems to be of definite value in removing membrane, getting rid of nasal discharge, and hence greatly reducing the infectivity of membranous rhinitis. But the vaccine does not appear to be capable of completing the work of elimination after the membrane has gone—i.e., after the vascular and lymphatic channels by which antibodies can reach the bacilli have been removed.

SCHOOL CLOSURE IN MEASLES.

BY A. BANKS RAFFLE, M.D. DURH., LL.B., B.HY.,
SCHOOL MEDICAL OFFICER, SOUTH SHIELDS.

To those working on the preventive side of medicine school closure as a means of controlling epidemics is always an interesting question. Opinions differ as to its efficacy even amongst medical men, and the present article is an account of how it worked in an epidemic of measles. Laymen, especially members of education committees, often meet our arguments in favour of school closure with the retort that the children are just as liable to be infected in their home life as they are to be infected in school. The

intercourse in the home, the street, the Sunday school, and places of amusement plays, of course, its part in the spread of infectious disease, but I hope to show that in the epidemic which is here considered it was a minor part.

During the spring and early summer of last year we had to control an extensive epidemic of measles, which affected 15 out of 21 of our infant schools. There were 858 children attacked, and each of the cases has been investigated for the purpose of a special report to be included in the annual report for 1911. I have analysed the figures of incidence in each school in the hope that other school medical officers will follow my example and give the profession figures of proof of the efficacy of school closure. The accompanying table shows the departments affected, the

Table showing the Influence of School Closure in an Epidemic of Measles.

Name of school.	Extent of closure.	Average attendance.	No. of susceptible children.	No. of cases before closure.	No. of cases within 14 days after.	No. of cases more than 14 days after.

extent to which they were closed, the rough average attendance of the department, the number of children who had not already had measles (from figures obtained during three years of medical inspection), the number of cases occurring before closure, the number occurring within 14 days of closure, and the number which occurred more than 14 days after the closure.

We must take into account, as I have already said, both the infection which may be present in the home life and that in the school life. If we eliminate one of these sources of infection we can then ascertain the part played by the other in spreading the disease, providing that we have remaining, after one source has ceased to act, a large number of susceptible children. During the period that a child is at school both sources of infection are in operation, and for a period of 14 days after the child is excluded it is still possible that the child was infected at school and has been carrying the undeveloped disease in its system. After the maximum period of incubation has expired all cases occurring amongst the children must be the result of infection in the home life.

There were in this epidemic 4470 children exposed to infection, and of these 2180 were susceptible to measles. Of these, 853 children were attacked, 638 cases occurring during the time that the children were at school and 140 during a period of 14 days after the school was closed; that is, 778 cases which might have been infected either at school or in the home life. Thus, at the time of the removal of the possibility of the infection at school there were still more than 1400 children who were susceptible to measles. Only 75 of these children actually contracted the disease. This shows, I think, the important part played by the school in the spread of the infection of measles and the value of school closure in this epidemic as a preventive measure.

South Shields.

AN OPERATION FOR HÆMORRHOIDS AND CHRONIC CONSTIPATION.

BY CHARLES AUBREY BUCKLIN, M.A., M.D.

THIS operation, which is described below as it has been performed, is designed for the relief of hæmorrhoids and chronic constipation when these are not caused by obstructive inflammatory changes or by neoplasms above in the intestinal tract.

The first instrument necessary is a bi-valve vaginal speculum which can be so forcibly distended with a screw mechanism that the grasping of the distal ends of the blades offers no serious resistance to the distending apparatus. The stem of the screw device of this speculum should be marked with a file so as to indicate when its blades are distended until they measure six inches about their distal ends. The size of six inches in circumference will be found to be a safe and sufficient distension of the sphincters of the anus for all well-developed persons over 15 years of age who are suffering from these diseases. The surfaces of the speculum blades must be smoothly finished and without any openings through them. The instrument should be disinfected and then allowed to become thoroughly cool, after which the blades should be immersed in melted beef or mutton tallow which has been previously heated sufficiently to sterilise it, and then allowed to cool down to the lowest temperature at which it will remain fluid before the blades of the speculum are immersed. The blades are thus covered with a coating of tallow. It has been clinically demonstrated that this method of greasing the blades prevents any accidental complication resulting from abrasions of the mucous membrane which have been caused by stretching the sphincters of the anus so extensively with instruments.

The patient having been prepared for this operation by taking upon retiring on the previous night the necessary cathartic is anæsthetised to the state of muscular relaxation. The greased blades of the speculum are instantly introduced just through both sphincters sufficiently to insure that they are stretched when the blades are expanded. Five minutes are taken distending the blades to the proper size. The screw is now reversed one turn which causes the blades to relax from their strong contact with the mucous membrane of the anus sufficiently to allow the speculum to be slowly rotated and manipulated for the purpose of exposing the lining of this opening for inspection. Hard stumps resulting from previous hæmorrhoids are removed with the forceps and a knife. Other forms of this disease are treated with the forceps and a No. 1 catgut ligature, after which the hæmorrhoids are cut off outside of the ligatures; or when the swellings are too numerous they may be treated with hypodermic injections of 30 per cent. of carbolic acid in alcohol. The slits made in the mucous membrane by operating are better closed by stitches of No. 1 catgut for the purpose of avoiding complications.

No further explanation of the methods of operating is necessary. The patient should be confined in bed for five days after the operation. A bandage has not been found necessary in cases that have been operated. The bowels should be locked up by giving a dose of one grain of opium morning and evening. The giving of opium should be commenced as soon as the patient is able to take the medicine after the operation. On the evening of the fifth day the opium should be discontinued and the patient should take a similar dose of the same cathartic medicine as was used at the commencement of this treatment. On the sixth day the patient can be discharged entirely free from any danger of the hæmorrhoids returning. When the trouble is chronic constipation it will rapidly disappear.

These results are attributable to the reduced action produced in the sphincters by their extensive stretching. The contractions are permanently reduced and the spasms with which the sphincters were constantly affected in both of these diseases are removed. Without having had clinical experience of these results no one can appreciate the physiological relief which attends stretching of contracted sphincters in diseases of this class.

New York.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY INTRAVENOUS INJECTION OF CHINOSOL WITH FORMALDEHYDE.

BY JOHN MCELROY, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

IN THE LANCET of Nov. 12th, 1910, I published the effects of the above treatment in three cases of pulmonary tuberculosis. Since then I have had 22 cases under my care, and I think the publication of my results may prove interesting. It is quite possible that these results would have been even more successful had my patients continued to follow out my directions, but so-called "friendly advice" in several instances intervened and prevented my doing as much for them as I could have done.

Regarding the three cases already published, Case 1 is still at his daily work and feeling as well as ever he did. Case 2 decided to try a sanatorium, and I lost trace of him, although in an indirect way I hear he has not made any more progress. Case 3 took a relapse and put himself under other medical care. Of the cases unpublished:—

CASE 4.—Male, aged 44. Both lungs affected; all right lung and upper left lobe. Abundant coarse moist râles over upper right lobe front and back with fine râles over all affected region. Temperature; sweats; profuse expectoration laden with tubercle bacilli. Pretty severe hæmoptysis on several occasions. Pleurisy. Loss in weight over a stone. Regular medical attendant's prognosis, "hopeless." Present condition: Adventitious sounds absent. Appetite good. Sweats absent; temperature normal. Cough and expectoration practically absent. Gain in weight 17¾ lb. Back at his own work for over three months.

CASE 5.—Female, aged 26. Had been in sanatorium for six months; no benefit derived. Upper and middle lobes of right and upper portion of upper left lobe affected. Dry râles over all affected region. Cough; sputum; tubercle bacilli present. Good deal of weakness with shortness of breath. Not much loss of weight. Present condition: complete absence of adventitious sounds; quite strong again. Gain in weight 6¾ lb. Sputum negative. Back to work.

CASE 6.—Male, aged 26. Ill two years. Hæmoptysis very often. Temperature; sweats; much shortness of breath; sputum positive. No appetite. Very weak. Upper and middle lobes of right lung affected. Dry râles. Slight loss in weight. Present condition: Temperature normal; sweats and hæmoptysis stopped. Appetite good. Breathing much better; feeling stronger. Adventitious sounds gone. Cough and expectoration almost absent. Doing light work.

CASE 7.—Female, aged 16. Ill for a year. Upper lobes right and left affected. Temperature; cough; expectoration; sputum positive. Never menstruated. Slight loss in weight. Regular medical attendant's prognosis, "hopeless." Present condition: Temperature normal; cough and expectoration absent. Last four months menstruated regularly. Gain in weight 6 lb. Adventitious sounds all absent. Back to usual occupation.

CASE 8.—Male, aged 36. Upper and middle right and upper left lobe affected. Temperature; sweats; hæmoptysis; shortness of breath; weak. Loss in weight. Cough and profuse expectoration; sputum positive. Regular medical attendant's prognosis, "hopeless." Present condition: Temperature normal; sweats stopped; no hæmoptysis. Breathing normal; weight normal. Cough and expectoration practically absent. Adventitious sounds disappeared. Able for work.

These cases all seem as if the disease has been arrested and point to the great benefit—to some patients—of the treatment. Of my 17 other cases 5 are improving, but it is too early yet to say how long this will continue as they are still under treatment. With regard to phthisis, seemingly more than to any other disease, any new treatment is criticised from the standpoint of a specific, but can we really say that there is a specific for any disease? I do not think so. Naturally one agrees we have heard of many cures for pulmonary tuberculosis, but they have been, in the majority of cases, unable to stand the test of time. If pulmonary tuberculosis is due to a specific microbe, why does the one treatment not have the same effect on all? This question opens up the query, Is tuberculosis due to a particular microbe? For a considerable period I have held to the opinion that while tuberculosis may be due to a particular micro-organism, yet there must of necessity be different species or varieties of such, else why do we get patients in whom the lung lesion is comparatively small having a most disproportionate systemic infection, resulting in a condition upon which no treatment seems to have any effect, and other cases in which the lung lesion is large, with a small systemic infection and most amenable to treatment? They cannot all be explained by the principle of mixed infection. No; the probability is that when our bacteriological knowledge is improved we shall find there are, as I have already said, various species of the tubercle bacillus, some of the species being more virulent than others. I am pleased to see from one of the journals that Mr. J. Penn Milton is working at a similar theory on practical lines, and I await with interest the publication of his results in this direction.

To enable whichever treatment we select to do the most good for the patient early diagnosis of the disease is of the utmost importance, and the leading specialists in tuberculosis will, I am sure, agree that "the good old clinic with its minute auscultation is the best means to make a good diagnosis." Tuberculin tests are of the greatest service in assisting a decision in a doubtful case, but X ray photography is of practically no value for that purpose, as consolidation of tissue must have taken place before it will reveal anything.

Belfast.

NOTE ON AN OPERATION FOR PHLEBITIS WITH THROMBOSIS.

BY SKENE KEITH, M.B. EDIN., F.R.C.S. EDIN.

Dr. George E. Keith asked me to see one of his midwifery nurses who was laid up by thrombosis with phlebitis in the superficial veins of the right leg, and it had occurred to him that it might be a good plan to cut out the clots and the inflamed parts of the veins. The history of the illness was that the patient (about 50 years of age) had a recent attack of influenza, sufficiently severe to keep her in bed. Ten days after the onset of the illness she complained of pain in the leg, and on examination Dr. Keith felt two large clots—one in the vein above the knee and the other in front of the middle of the leg. The skin was red and swollen, but when I saw her, a week after the clots had been first discovered, the redness had lessened somewhat. The clots were nearly an inch each in length and there was a third small one near the ankle. The veins of the leg were slightly varicose, and there was a very small amount of œdema.

I have not noticed if veins have been removed in this condition, and the operation does not appear to be mentioned in the latest surgical works, but it seemed to me a most reasonable suggestion as it was important that the nurse should not be laid up in bed for an indefinite number of weeks, and the risk of removing a few inches of vein is certainly not greater than allowing a clot to absorb with the accompanying risk of separation. The only point which is doubtful to me is whether the saphenous vein should be tied first. In a markedly varicose condition of the veins I would certainly do so, but in an ordinary case it hardly seems necessary, provided that the vein is exposed and tied well above the clot.

In the case referred to there was no difficulty in the operation, and the veins were much thickened where the clots were situated. Immediately on the proximal side of the clots the veins were normal, thickening towards the distal end and continuing in this state for some distance beyond. As very slight pressure caused the clot to slip out of the vein, it showed how carefully such conditions must be handled. The patient was able to walk ten days after the operation.

This operation seems to be such a useful one that, even if the idea is not original, it is well worth drawing attention to it.

Upper Berkeley-street, W.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Hereditary Ophthalmoplegia in Five Generations.—Crystal-like Bodies of Radiate Structure in the Lens.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 25th, Mr. J. B. LAWFORD, the President, being in the chair. It was announced that the society had accepted the invitation of the Dublin members to hold the May meeting on the 11th of that month in Dublin.

Mr. A. A. BRADBURNE read a paper entitled "Hereditary Ophthalmoplegia in Five Generations." In this family there was a condition of ptosis accompanied by an almost complete loss of the ocular movements, which had been present in five generations. After enumerating the numbers affected and briefly describing the condition in each, he proceeded to consider the various types of this rare affection. He classed anomalies of congenital ocular immobility into three divisions: first and most common, those in which only ptosis was present; secondly, when this was combined with epicanthus; and thirdly, a type in which ptosis might or might not be present, but in which the ocular movements were very defective or altogether wanting. This latter type embraced three sub-divisions: (*a*) ptosis associated with defect of the superior rectus; (*b*) more extensive involvement of the eye muscles with or without ptosis, the condition being due to some nerve lesion; and (*c*) this type included the same kind of anomalies, but the condition was due to entire absence of, or very defective development of, the muscles. His own case came under this category. Mr. Bradburne pointed out that in two of the younger members a certain return of the movements had occurred, and suggested how this might have come about. He showed that in the shark the ocular muscles arose from three centres—one for the superior obliques, one for the abductors, and the remaining four muscles arose in pairs from a third. These paired muscles were the superior with the internal rectus and the inferior rectus with the inferior oblique. In all the members of this family the superior obliques were probably present, and hence if any further movements became possible one would expect their appearance to follow somewhat the lines as seen in the shark. In one of the members of the family it had done so, as one eye was able to move from a point straight in front outwards, thus seemingly pointing to a development of the second centre. But that did not follow in another case in which both eyes possessed full lateral motion. By analogy one would expect to find development of motion in the upward direction, but such was not present. Hence the human development was from a different centre to that of the shark, or another factor was present in the case. As the patient had ptosis, motion in an upward direction would not be of much practical use, hence it seemed as if the visual act had had something to do with the "evolution." This seemed probable, as in the same case, to prevent diplopia, the visual act had produced a convergent squint. Finally, he asked if the argument could be logically reversed and the condition of muscle palsy attributed to a long-continued non-use of the eyes in some ancestor afflicted with ptosis.—The paper was discussed by Mr. N. BISHOP HARMAN, who pointed out that in the sunfish each of the recti, except the rectus externus, sent off a separate slip which went to the circular fold round the eye, and was capable of retracting a fold from the cornea, and one saw the original development of the levator. The idea of an arrest of development running through a family was easier of acceptance than the more difficult theory which Mr. Bradburne had brought forward.—Mr. W. M. BEAUMONT (Bath) suggested the condition might not be so much a pathological one as a tendency in this family to a throw-back to a primeval condition antecedent to the development of the oculo-motor muscles.

Mr. GEORGE COATS read a paper entitled "On Crystal-like Bodies of Radiate Structure in the Lens." He said they were found in a hypermature cataract in a woman, aged 69, and had not been seen clinically. In the lens nucleus, which had undergone but little degeneration, round and oval bodies, measuring from 0·035 to 0·160 mm., were found. They had a refractile crystalloid appearance and were marked by numerous fine lines converging towards an axial linear streak or spot. There was frequently a tendency to cleavage along these lines, so that the body was split up into a number of radially disposed pyramidal sectors, not unlike the pyramids of the kidney. In the larger crystals there was a central tuberculated mass of mineral hardness, the structure resembling that of a rubber-cored golf ball. Usually the adjacent lens fibres were arranged round the crystals to form a kind of capsule. Only two similar observations were on record, in one of which the bodies were seen clinically as globular beads with a silky or pearly sheen. In all these cases the lens was cataractous; in two the opacity was senile, in one lamellar, the patient being a child of 6. In all the crystals were confined to the more central layers of the lens. As to the nature of the crystals, the scarcity of material made it impossible to carry out extensive histo-chemical researches, but they showed considerable structural resemblance to leucin, a diagnosis which was sufficiently probable, since the crystals occurred in cataractous lenses, and leucin is a product of proteid disintegration. They occurred, however, in the least degenerate part of the lens. Hydrochloric acid produced no effervescence. Dr. W. H. Willcox had kindly examined the specimens, and reported that the appearance of the bodies was "similar to that which leucin takes when it has been subjected to dehydrating processes."—The PRESIDENT asked whether Mr. Coats found these bodies in the extracted lens—i.e., whether the eye had been removed.—Dr. J. BURDON-COOPER (Bath) asked if Mr. Coats had ever found tyrosin in the lens. He had himself discovered that substance in the aqueous after needling for lamellar cataract. Professor W. D. Halliburton, of King's College, confirmed that it was tyrosin. In wondering how tyrosin could have got there, it occurred to him (the speaker) that possibly it was the result of hydrolysis of the lens, and he therefore sent for a pig's eye at the butcher's, and found the lens yielded almost pure tyrosin. The microscope gave the most delicate test for it. Tyrosin was fairly soluble in sulphuric acid. He had found the substance in the lens in all cases of cataract, and he was strongly of opinion that the change which took place in senile cataract was a hydrolysis of the lens.—Mr. COATS, in reply, said there was nothing in his sections which resembled tyrosin.

The following cases and card specimens were shown:—

Mr. A. C. ROPER: Melanotic Sarcoma of the Conjunctiva with Secondary Nodules in the Skin. There was no trace of anything in the fundus. He was advised radically to remove the whole of the orbital contents. The skin nodules were found not to be malignant.

Mr. COATS: (1) Concretions (Drusen) of the Papilla; and (2) Corpora Amylacea in the Retina.—Dr. E. FARQUHAR BUZZARD said the appearance was different from corpora amylacea in nerve tissue generally, as in this case there was a definite capsule.

Dr. RAYNER D. BATTEN: A Fixation Fork, designed for the insertion of sutures in the sclerotic in advancement operations. By its aid one could pick up exactly the amount required, and there was no danger of the needle being pushed in too deeply. He also showed a case of Central (Macular) Coloboma of the Choroid of unusual form, symmetrical in the two eyes.

Lieutenant-Colonel J. L. PISANI, I.M.S., showed a case, which was originally exhibited in 1880, with peculiar bodies on the iris after needling for lamellar cataract.—Mr. M. S. MAYOU thought the bodies might be due to implantation of the cells of the capsule on the iris.

Mr. R A. GREEVES: (1) A case of Metastatic Septic Choroido-retinitis; and (2) a case of Quinine Amblyopia.

Mr. COATS: A case of Tubercle of the Choroid in a Cat.—Mr. MAYOU related a case in a cat also, which bore out Mr. Coats's remark. In that case, however, there was a small nodule in the breast. He thought it was not likely for primary tubercle to start in a choroid without there being a lesion elsewhere in the body.

Mr. C. WRAY: (1) A case of Glaucoma; (2) a case of Keratitis Disciformis; and (3) a case of Exostosis of the Roof of the Orbit.

Mr. R. R. JAMES: A case of Hyaline Degeneration of the Disc.

Mr. C. A. HORSFORD: A case of Mal-Development of the Eyes in a child.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Hydatidiform Mole.—Heath's New Treatment for Paracutic Deafness.

THE annual meeting of this society was held at the Royal Devon and Exeter Hospital on Jan. 12th, Dr. R. V. SOLLY, the President, being in the chair.

The honorary secretary's report for the past year having been read and adopted, the following officers were elected for 1912:—President, Dr. R. V. Solly; Vice-President, Dr. C. J. Vlieland; honorary secretary, Mr. G. L. Thornton; honorary treasurer, Mr. Ransom Pickard.

Mr. G. L. THORNTON read notes on a case of Hydatidiform Mole. The patient, a married woman, aged 36 years, was first seen by Mr. Thornton in response to an urgent summons on June 28th, 1911. On arrival the patient was found to be lying on a sofa downstairs blanched and collapsed. There was every evidence of severe flooding not yet arrested. A cursory examination showed that the abdomen was enlarged to above the umbilicus with a (?) pregnant uterus. In addition there was massive soft œdema from the waist downwards. The condition being one of extreme gravity, the vagina was at once plugged with strips of gauze wrung out in 1-4000 biniodide of mercury, and ergotinine cit. gr. 1/100 was injected intramuscularly. The patient was then removed in an improvised ambulance to the Exmouth Cottage Hospital. The notes on admission showed nothing of note in the family history, whereas the patient herself had never had cause to consult a medical man previously. She was married at the age of 25 years. There were six children born at full term and all living, and there had been no miscarriages; all deliveries had been easy and natural. Catamenia had begun when the patient was 14 and had been regular as a rule. The bowels acted regularly, and as regards alcohol she was a total abstainer. The last child had been born on Oct. 2nd, 1909. She had nursed until May, 1910. Catamenia had returned again in June, 1910, and remained regular until April, 1911, when she menstruated early in the month. Although occupying the usual period with her of seven days the menses were scanty. About the middle of May there had been a sudden severe flooding, and since then constant oozing with actual flooding on some days and a mere show on others. She had noticed no clots and no material other than blood. During the first week in May (and prior to the first flooding) she felt sick and vomited after food. This sickness was accompanied with frontal headache which had since remained constant. The sight had remained good. About three weeks before admission she first noticed swelling of both feet and shortly afterwards of the legs and thighs. For about a fortnight she had noticed that the abdomen had been increasing in size. She had felt no movements and did not consider that she could be pregnant. There had been no difficulty in micturition and the bowels had remained regular. On June 28th (the day of admission) a severe flooding occurred when she was at work in the kitchen. She became faint and collapsed, in which condition Mr. Thornton shortly found her. "The present condition on admission" noted that she was a very pale woman, well nourished, with slight puffiness of the eyelids. There was dyspnœa, but no thorough examination of the lungs could be made (subsequently œdema of both bases was noted). Save for a low-pitched systolic murmur over the præcordium and a banging first sound, there was nothing to report as regards the heart. The pulse, which was very rapid when first called to her, had steadied down to 80 two hours after the ergot injection. The abdomen was distended from one inch above the umbilicus downwards. Both flanks were resonant. The swelling was of the size of a pregnant uterus at the sixth month, and could be felt to harden on palpation. Occasionally it gave a somewhat doughy impression. Low down on the right there was exquisite tenderness to even superficial palpation. Per vaginam the cervix felt like that of the second or third month. The os externum was patulous to the tip of the index finger. There was no *ballottement*, and the examining finger encountered everywhere the same doughy consistence as that noted per abdomen. A sample of urine was found to be of specific gravity 1016 and to show "solid" albumin on boiling. Plentiful hyaline, granular, and a few epithelial and blood casts were noted in the centrifugalised deposit. Hydatidiform or carneous mole was considered from the first to be the most probable diagnosis, and, indeed, no likely alternative seemed to be forthcoming. It was decided to endeavour to improve the general condition and to avoid operative interference for the present. Biniodide douches were ordered and a mixture containing digitalis, citrate of potash, and liquor ammon. acetatis was given, and the patient was placed on a milk diet. There was no further hæmorrhage during the first week following admission, and the general condition improved as regards lessening of œdema and decrease in albumin. The quantity of urine barely yet, however, exceeded a pint. On July 4th, following on the advice of Mr. A. C. Roper (consulting surgeon to the hospital), who had kindly taken an interest in the case throughout, ergot was added to the mixture and a few pains followed the same night. Labour pains did not, however, set in fully until the early hours of July 6th, when Mr. Thornton was called to her at about 3 A.M. The mole had then been rapidly expelled in three portions with considerable hæmorrhage, but after expression of some clots and a small remaining portion the bleeding was soon arrested and a firm contraction of the uterus was obtained. The condition was an anxious one for about 24 hours, and hypodermics of strychnia were given eight-hourly. The subsequent history was uneventful, œdema and albuminuria both clearing up gradually and the quantity of urine passed increasing to two pints and upwards within three days. The temperature, which had been of an intermittent type from the time of admission, did not reach normal until the first week in August. One sudden rise to 104·8° was noted on July 20th and was difficult to account for. The patient was discharged from hospital on August 15th, and subsequently was observed as an out-patient under Mr. Thornton's care at the Exmouth Dispensary. In September no traces of renal disease could be found, but the uterus had again cropped up above the brim. To exclude possibility of chorionic epithelioma the patient was now sent to the Samaritan Free Hospital, London, under the care of Dr. G. F. Darwall Smith, who curetted and received a favourable report from the pathologist. The woman was at the present time menstruating regularly and in apparent sound health. The points about the case were: (1) The rarity of hydatidiform mole—1 in 2000 deliveries, according to Galabin and Blacker; and (2) the obscure causation. The history of this case suggested the nephritis being consequent upon the establishment of a molar pregnancy, and the same arguments could be advanced for the renal condition as were upheld in cases of puerperal eclampsia. If the placental auto-intoxication theory held good in eclampsia, where most often nothing abnormal could be found, how much more easy would be its explanation in cases of molar pregnancy and the extensive chorionic degeneration concerned with it. The irregular chart again suggested an infection. As regarded treatment, there was nothing to regret, and the only comment to make was the immediate response to ergot both as regards the initial hæmorrhage and the subsequent emptying of the womb. A careful subsequent examination by a skilled gynæcologist was suggested in a condition which, according to the text-books, is followed by chorion epithelioma in 60 per cent. of the recorded cases.—The PRESIDENT spoke of an allied condition to chorion epithelioma occurring in the testicle of a man. In his opinion he did not think that vesicular mole was as rare a disease as the text-books made it. He had come across three in his own experience.—Dr. J. D. HARRIS mentioned a case where a part only of the placenta was involved.—Mr. C. E. BELL supported the contention in the matter of rarity, and he did not agree in the figures given for the incidence of chorion epithelioma.—Mr. THORNTON replied.

Mr. ROBERT A. WORTHINGTON read a paper entitled "A Note on Mr. Heath's New Treatment for Paracutic Deafness." He briefly described the chief theories as to the cause of paracusis Willisii, and contrasted that of Heath with that of Politzer and with Gray's more philosophical development of Politzer's theory. He said that Mr. Heath appeared to consider the essential causes of paracutic deafness to be a loosened ossicular chain and a lowered tension in the labyrinthine fluid content, the latter being dependent on the imperfect action of the stapedius muscle induced by the former. He pointed out that the early onset of

paracusis in otosclerosis, a disease of definitely observed morbid anatomy, appeared to render the hypothesis of a loosened ossicular chain untenable. With regard to the tension of the labyrinthine fluids, the continuity of the latter with the cerebro-spinal fluid appeared to render it unlikely that any change in tension could be of more than momentary duration. On anatomical grounds, too, it seemed probable that the action of the stapedius was such as to tilt the stapes away from the oval window, which would tend to lower rather than raise labyrinthine tension. If the labyrinthine tension could be raised for an appreciable time by the movements of the stapes, then it would be by such an experiment as Cyelle's, and in this, as is well known, the perception of sound is diminished, not increased. Although he disagreed with Mr. Heath's theories the complexity of the subject was such that he felt that the treatment Mr. Heath had advocated might turn out to be of value on quite other theoretical grounds. He then described in detail two cases of paracusis with thin flaccid tympanic membranes which he had treated by painting with cantharidin solutions according to Mr. Heath's method. During the treatment the patients became very deaf indeed in the ear to which it was applied; at the same time, however, the tinnitus which had been a marked symptom disappeared. As the inflammatory processes were allowed to subside the hearing gradually returned, as far as the ordinary tests went, to exactly what it had been before. Both patients considered, however, that they heard better, and having lost their tinnitus were at first very pleased. Unfortunately, the tinnitus all returned again within a few weeks of ceasing treatment. Mr. Worthington was further of the opinion that the improvement in hearing was more imaginary than real, and due to the contrast with the high degree of deafness during treatment.—The PRESIDENT and Dr. HARRIS discussed the paper and Mr. WORTHINGTON replied.

Mr. G. A. THORNTON exhibited blood film stained to show crescents from a case of Malaria under his care.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Cæsarean Section.—Retroversion of the Uterus.

A MEETING of this society was held on Jan. 19th, Dr. A. DONALD (Manchester), Vice-President, being in the chair. Dr. Arnold W. W. Lea (Manchester) was elected President for the ensuing year.

Dr. A. STOOKES (Liverpool) related the details of two cases of Cæsarean Section. The first case was that of a woman, aged 30 years, who had had three normal labours and who gave no history of trouble in the present pregnancy. The patient was seen at 5 A.M. by two medical men, who found her with strong labour pains and the vagina blocked by a tumour, so they sent her to the maternity hospital. On admission it was found that an arm was presenting and that the vagina was blocked by a soft fibrous mass which passed within the cervix; no pedicle could be reached. The general condition of the patient was fairly good; she was pale and the pulse-rate was about 100. The abdomen was larger than usual, but not tender. Cæsarean section was done and a dead child was extracted weighing 6 lb. 6 oz. After removing the placenta and membranes the tumour was found to have an extensive attachment to the posterior wall of the uterus, so supravaginal hysterectomy was done. The patient died from shock eight hours later. In the second case the patient, who was 42 years of age, had had eight normal labours. She was vomiting incessantly and was constipated; the bowels had moved slightly two days previously. The abdomen was not enlarged more than a full-time pregnancy and there was no hyper-resonance. Operation was decided upon as it was thought that there must be intestinal obstruction. After a dead child weighing over 7 lb. had been removed the peritoneum was found to be salmon pink in colour and studded with small yellow spots. The whole of the small intestine was empty and collapsed. The large intestine was attached by a mesentery 7 in. in length, which allowed the caput cæcum to fall into the pelvis. It was thought by Dr. Stookes that this must have caused incomplete obstruction, and that the empty state of the bowels was due to the reversed peristalsis, but he now believed the explanation offered by Mr. A. N. Cuff to be the probable one—that the woman was suffering from acute pancreatitis. The patient recovered from the anæsthetic and said she was much relieved, but she died next day from exhaustion.

Miss M. H. F. IVENS (Liverpool) read a paper analysing 100 Consecutive Cases of Retroversion of the Uterus, treated by round ligament ventro-suspension (Gilliam's operation), in which the after-history had been ascertained in 93 cases. There had been no mortality; 93 had healed by primary union, and in one case only had relapse occurred owing to the tenuity of the ligaments. In 32 uncomplicated cases the results were most satisfactory, while in 11 associated with marked prolapse the uterus was held up well by the round ligaments, which showed extreme hypertrophy after operation. In 46 cases where adnexal disease was present good results were obtained in all but the gonorrhœal cases, where further inflammatory trouble took place in 11 instances, although the uterus maintained its position. In 3 cases out of 4 with uterine fibroids myomectomy, followed by Gilliam's operation, was successful; the fourth subsequently required hysterectomy for a submucous sessile tumour. In 20 instances pregnancy had since occurred. Of these, 11 had borne children with no difficulty, 6 were still pregnant, and 3 had had abortions. As no ill after-effects were present in the 93 cases followed up it was concluded that the operation was a safe and successful one when done under suitable conditions, and could be undertaken during the child-bearing period. From a careful consideration of the history and symptoms of the cases recorded it was also concluded that in the majority of instances even a simple retroversion of the uterus ultimately caused pathological changes in the pelvic organs, beginning with passive venous congestion, and that for this and other reasons therefore required treatment.

LIVERPOOL MEDICAL INSTITUTION.

Recurrence of Adenoids.—Tuning-fork Vibration and Auscultation.—Opening of Skull in Cases resembling those of Tumour of the Brain.

A MEETING of this society was held on Jan. 25th, Mr. ROBERT JONES, the President, being in the chair.

Mr. THOMAS GUTHRIE read a note on the Recurrence of Adenoids, in which he pointed out that recurrence was seen most commonly in children operated on under the age of four years, even when the operation had been as complete as possible. Recurrence was not frequent in those between four and seven years of age, and practically did not occur in patients over seven where the operation had been thorough. Mr. Guthrie showed a photograph of the naso-pharyngeal tonsil removed from a child of three and of the growth which recurred at the age of five. He pointed out that recurrence was favoured by attacks of the specific fevers, by congenital syphilis, and by anterior nasal obstruction from bony deformities, &c. He urged after-treatment of posterior nasal catarrh and attention to the general health conditions of the patients.

Dr. R. J. M. BUCHANAN read a note on, and demonstrated the method of, Tuning-fork Vibration and Auscultation. He used a fork of "A" pitch, which was struck, and the stem placed on the part to be examined; the stethoscope was applied, and the fork moved by small steps over the part. The sound vibrations varied with the nature of the part over which the fork was resting. Dr. Buchanan claimed for this method that it was possible to map out organs accurately, to differentiate solid from liquid, the colon from small intestine, the stomach from the colon. He could map out portions of consolidated lung and mediastinal tumour. In one case he had been able to make out alteration in the size of a kidney which had been verified by separation of urine and by the findings at the operation.

Dr. W. B. WARRINGTON read a paper on the Results of 17 cases in which the Skull had been Opened for Symptoms resembling those of Tumour of the Brain. The operations had been mainly done by Mr. Keith Monsarrat. Of 9 cases of cerebellar exploration death took place soon after operation in 5; in these the diagnosis was confirmed by post-mortem examination and in 2 by the findings at operation. In 4 cases the patients recovered; 3 were alive and well with

the vision preserved; 1 went blind (in this patient nothing was found at the operation though bilateral exploration was made). In 2 of these successful cases nothing was seen at the operation; in 1 a tumour was diagnosed and found on the left side of the cerebellum. Of 8 cases of cerebral exploration 4 were fatal within a month. In 1 a tumour in the right parietal region was partly removed with relief of agonising pain, the patient living a year. In 3 cases where no gross lesion was found at the operation relief was obtained from the symptoms: 1 patient alive and well with improved vision five years after operation, another three years after operation, and 1 died a year after with right hemiplegia. Dr. Warrington had found that advanced cases did not improve in vision and in the condition of the discs, but where the operation was done in the earlier stages of the alterations improvement was to be looked for as the result of a decompression operation.

Considerable discussion took place, in which Mr. THELWALL THOMAS, Mr. DAMER HARRISSON, Mr. E. STEVENSON, Mr. H. E. JONES, Dr. N. P. MARSH, Dr. J. H. ABRAM, Mr. R. M. STOCKDALE, Mr. R. W. MURRAY, Mr. C. G. LEE, and Dr. H. R. HURTER took part.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 19th, Dr. A. Freeland Fergus, the President, being in the chair.—Mr. A. Ernest Maylard showed a boy, aged 10 years, who had been admitted to the Victoria Infirmary in September last suffering from an extensive Compound Comminuted Fracture of the Cranial Vault in the right parietal region, with escape of brain tissue, and signs of fracture of the base of the skull. At the operation the extruded brain matter and depressed fragments of bone were removed and other portions of bone elevated. The wounds remained aseptic throughout, but the boy was delirious for some days, and for a fortnight was not expected to survive. Thereafter he made a good recovery, and when shown, about three months after the accident, was mentally acute and physically active.—Dr. R. Speirs Fullarton showed a boy, aged 9½ years, who during the past three years had had three attacks of Hæmaturia, and now had a large tumour in the region of the right kidney, which was said to have been noticed first about three months ago. The diagnosis was thought to lie between cystic kidney, malignant tumour of the kidney, and hypernephroma.—Dr. Fullarton also gave a short account of the albumin-reaction of the sputum in pulmonary tuberculosis, and said that his observations made in 50 cases of phthisis and 50 cases of chronic bronchitis and other non-tubercular pulmonary affections confirmed the statements of continental observers that in the great majority of cases of phthisis and in pneumonia during the acute stage albumin is present in the sputum in considerable amount; while in the majority of cases of non-tubercular conditions (excepting pneumonia) albumin is either absent or is present in trifling amount. The proportion of cases in which this rule did not apply was, however, sufficiently large (as had been shown by Dr. Nathan Raw and as the speaker had found) to diminish seriously its value in the differential diagnosis between tubercular and non-tubercular diseases of the respiratory organs.—Dr. J. H. Nicoll showed: (1) Three examples of Meckel's Diverticulum which had been removed in consequence of having caused intestinal obstruction; (2) a large Mesenteric Fibro-sarcoma, with three-fourths of the small intestine necessarily removed with it; (3) Masses of Lymphatic Vessels excised in a case of Filarial Lymphangiectasis of the Spermatic Cord; (4) Calculi of Unique Composition removed from the Bladder in a case of Prostatic Hæmaturia; and (5) a large number of specimens from recent cases in which "piecemeal" prostatectomy had been performed. Dr. Nicoll strongly recommended the piecemeal method of removing the prostate, of which, he said, surgical opinion was increasingly in favour.—Dr. G. H. Edington showed a specimen of an Old Fracture-dislocation of the Upper End of the Humerus, and photographs of a case of Old Fracture of the Patella, with wide separation of the fragments.

UNIVERSITY COLLEGE, DUBLIN (NATIONAL UNIVERSITY OF IRELAND), MEDICAL SOCIETY.—A meeting of this society was held at the Medical School, Cecilia-street, on Jan. 25th, Dr. John O'Donnell being in the chair.—Mr. Maurice R. J. Hayes read a paper on the X Ray Diagnosis of Diseases of the Chest. After demonstrating by means of lantern slides of skiagrams the x ray appearances of the normal chest, he went on to describe the appearances in early phthisis, pleurisy, aneurysms, tumours, diseases and foreign bodies in the œsophagus, &c. He held that phthisis could be recognised by the fluorescent screen even before physical signs could be detected. In these cases the apices were seen to go through the stages of brightness, transradiancy, blurring, and deep shadow, while the diaphragm could be seen to lose its normal regular variation and to become jerky or "cog-wheel" on the affected side. He also emphasised the importance of the left oblique position—viz., tube to the left behind and screen to the right in front—in diagnosis of aneurysms of the arch of the aorta.—Mr. T. T. O'Farrell showed specimens of Mediastinal Tumour, Aneurysms, and Fish-bone Perforation of the Intestine.—A discussion followed, and was partaken in by Mr. M. F. O'Hea, Mr. G. Maguire, Mr. O'Farrell, Mr. H. S. Meade, Dr. W. D. O'Kelly, and Dr. H. L. Barniville.

Reviews and Notices of Books.

Breeding and the Mendelian Discovery. By A. D. DARBISHIRE, M.A., Demonstrator of Zoology and Lecturer on Genetics at the University of Edinburgh. London: Cassell and Co., Limited. Illustrated. 1911. Pp. 282. Price 7*s.* 6*d.* net.

HOWEVER different opinions may be upon the interpretation and general bearings of the facts dealt with in this book the author must certainly be credited with having set forth an admirably clear statement of his subject-matter. Mr. Darbishire's style is of a high order, always lucid, and never prolix. It is not too much to say that this work, although "intended to serve merely as an introduction to the subject," seems to be the best exposition of "Mendelism," from the Mendelian point of view, that has as yet appeared; it is free from any tone of sectarian fervour, and makes no exclusive claim of infallibility for hypotheses which happen to be founded on experiment. Experiment is a mode of making observations, and explanations founded on data thus furnished are as liable to error as those founded on any other verifiable facts. These qualities of clear statement and temperate advocacy should strongly commend this book to the notice of all students desirous of informing themselves of the basic facts on which the Mendelian hypothesis has been raised. Hence this work has a definite value quite apart from the specific object aimed at by the author.

Mr. Darbishire states at the very outset that his object is "to place within reach of the practical breeder some of the things found out by the scientific student of heredity which are likely to be of service to him." Bearing this in mind we cannot perhaps quarrel with the author for the scanty and scarcely critical treatment which he gives to certain important considerations connected with or underlying his main subject. These considerations, however, he apparently admits to be important. After the preliminary statement of his object, as above quoted, he proceeds to say that the breeder has two methods, "selection" and "crossing," and that selection creates something new, while crossing merely re-combines characters which already exist. Very little or nothing is known (he says) "of the causes which determine the origin of new characters, either in the domesticated or natural state; but the art of breeding by re-combination of existing characters has been brought to a point of extreme precision by Mendel's discovery." This statement concerning "recombination" seems somewhat magisterial as it stands; the defined scope of the book, however, may be held to account for this assumption.

Again, after repeating that his object is to "make

perfectly clear what the Mendelian discovery was, and how it affects the practice of breeding," the author announces that he "will deal with the origin of new forms, because a knowledge of Professor De Vries's observations on this process is necessary to an appreciation of the significance of Mendel's discovery." On this follows at once an excellently clear statement of the hypothesis of *Mutationism*, which is so intimately associated with Mendelism in many, if not most, Mendelian writings. But here Mr. Darbishire, by omitting all critical comment on this new hypothesis of the origin of species, will leave many readers in some doubt as to how much importance he attributes to it himself, and how far it is bound up in his own mind with the Mendelian theory to the application of which he devotes the rest of his book. Again, in dealing with the matter of "Reversion," the author gives several instances and writes with his usual clearness; but other aspects of the questions involved are not discussed: he states that he has been merely concerned to point out that certain cases of "reversion" can be easily described in terms of Mendelian hereditary processes. In another place he says that though the Mendelian theory of "reversion" is not proved, it is, in his opinion, the first consistent theory which has been set forth. Here Mr. Darbishire certainly avoids any charge of dogmatic statement, but nevertheless the underlying assumption is of high importance to his general position.

After two interesting and ably written chapters (XV. and XVI.) on New Principles of Breeding, based on Mendel's Theory and on the Inheritance of Sex, the book ends with a very short chapter on the Origin of the Mendelian Mode of Inheritance. This chapter, consisting of but seven pages, begins with the statement that "it is a very important matter to determine whether Mendelian heredity is a fundamental process the true understanding of which will render all other phases of heredity intelligible, or whether it is an anomalous phase of heredity which is restricted to a small group of characters belonging chiefly to domesticated animals and plants. For if the latter is the case the investigation of Mendelian phenomena can throw no light on the problem of the successive generations of organisms, nor help to elucidate the nature of the processes to which evolution is due." Here Mr. Darbishire, in support of what apparently is his own view on this all-important question, singles out one opponent, Dr. Archdall Reid, and attacks him without great effect. Quite apart from the fact that the question to be decided does not turn necessarily on any views which may or may not be proper to Dr. Reid alone as to the question of sex-inheritance, and also apart from the fact that large numbers of biologists do not consider that Mendelism with all that it seems to entail is the true key to the process of biological evolution, it appears to us that Mr. Darbishire really fails to understand what Dr. Reid himself means. This may be to some extent Dr. Reid's fault. Mr. Darbishire is misled by words to oppose the "massive" as applied by Dr. Reid to evidence gathered from all available and relevant sources, to the "minute" evidence relied upon by himself in the matter of the observation of chromosomes, thus using a false antithesis. And we do not see that he is justified in attributing to Dr. Reid the belief that the *a priori* method of reasoning is trustworthy. But Mr. Darbishire does not expand this statement, and what he conceives the *a priori* method to be remains very doubtful.

In this interesting book the author is unquestionably at his very best when he deals, as in far the larger part he does deal, with the object he professedly undertook. But when touching, as he evidently thought it necessary to touch, on the wider biological questions concerning the origin of new forms, his judicial attitude seems to fail, and he appears to imply that the important question he raises as to the fundamental part played in heredity by the Mendelian process is already answered in the affirmative.

The excellent plates, in colour and in black and white which illustrate this book will be highly appreciated by all students.

Archives of Neurology and Psychiatry, from the Pathological Laboratory of the London County Asylums, Claybury, Essex. Edited by F. W. MOTT, M.D. Lond., F.R.S., F.R.C.P. Lond., Director of the Laboratory and Pathologist to the London County Asylums, Physician to Charing Cross Hospital, &c. Volume V. London: P. S. King and Sons. 1911. Pp. 226, exclusive of Appendix of Collected Papers.

VOLUME V. of the "Archives of Neurology and Psychiatry" maintains that high level of scholarship which our experience of its predecessors has led us to anticipate. It bears witness to the health and progressive vigour of neurological and psychiatrical research in the laboratory of the London County Asylums, under the ægis of its able director, Dr. Mott. In this volume 11 papers of varying length are published for the first time, and in an appendix seven others are republished, some of which have already appeared in the pages of THE LANCET. Of the former, reference may be made to the authoritative communication on Congenital Syphilis and Feeble-mindedness, from the pen of Dr. Mott. He shows conclusively that syphilis is an active agent in the production of congenital weakness and the degeneracy that accompanies it, and furnishes evidence to prove that the measure of its influence ought not to be estimated only by the visible and characteristic signs of syphilis on the body. The whole article deserves to be read carefully.

Other valuable papers are those on Institution Dysentery, by Dr. J. P. Candler and Dr. G. Dean, in which the same organisms as have been found in summer diarrhœa are reported as occurring in certain cases of epidemic intestinal dysentery at Claybury; on the Cortex of the Auditory Centre, the Insula, and Broca's Convolution in a Case of Deaf Mutism, by Dr. Fortuyn, of Amsterdam; on the Microscopic Investigation of a case of Tabo-paralysis with Bilateral Ophthalmoplegia, by Dr. Rondoni, of Florence; while the psychiatrical side is worthily represented by papers on the Psychological Conception of Insanity, by Dr. Bernard Hart; on "Washing Hand" Mania, by Dr. G. F. Barham; on Dementia Præcox, by Dr. Harper-Smith and Dr. G. H. Rae Gibson. In the appendix are Dr. Mott's Oliver-Sharpey lectures on the Cerebro-spinal Fluid, his Huxley lecture on the Hereditary Aspects of Nervous and Mental Diseases, and his Royal Institution lecture on Heredity and Insanity, as well as important pathological papers on Trypanosome and Spirochæte Infections, and on Amaurotic Family Idiocy, by the same author, and others that will equally well repay perusal by the neurologist and the physician.

Medical Science of To-day: A Popular Account of the More Recent Developments in Medicine and Surgery. By WILLMOTT H. EVANS, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital and Surgeon to the Hospital for Diseases of the Skin, Blackfriars. With 31 illustrations. London: Seeley, Service, and Co., Limited. 1912. Pp. 319. Price 5*s.* net.

"SUCCESS in carrying out the preventive measures which medical science has indicated does not depend only on members of the medical profession. It depends on the Government, on every voter in the Kingdom, and on every individual citizen, for without the coöperation of those who govern and those who are governed medical men can do nothing." In these words Mr. Willmott Evans strikes the keynote of his recent work, "Medical Science of To-day." With this point in view the education of the public in medical principles becomes a matter of the first importance, such

education being not in the details of disease as affecting the individual and their treatment, a practice which the medical profession must continue to deprecate as leading to injurious introspection, but in the broad facts on which our knowledge of disease is based and the methods by which that knowledge is attained, for these only can inspire confidence in the workers and obviate despair over temporarily conflicting views and theories. To this end Mr. Evans's book can be warmly commended for general perusal, the wider the better; to legislators (particularly those concerned especially with public health problems), to those whose function is the instruction of the community, schoolmasters, philanthropists, clerics, writers, and journalists. Mr. Evans says: "If we agree that the mainspring of the opposition to hygienic measures, whether that opposition is intentional or not, is lack of knowledge, it is clearly only reasonable that means should be taken to educate the public mind on some, at least, of the matters which are now engaging the attention of the medical profession, on some of the problems which we are now endeavouring to solve. ..... Though naturally legislators must be, for the most part, dependent on the expert opinions with which they are supplied, yet they would probably be more ready to accept those opinions if they were more able to appreciate the grounds on which those opinions were based." Our readers will here be in accord with the author.

All study of a subject should begin with at least a bird's-eye view of its history, explaining the course of its development, and Mr. Evans gives such a brief, though for the purpose ample, sketch before discussing the causes of disease, which he divides into four classes—mechanical, physical, chemical, and parasitic. Among the parasitic are, of course, included germs, and these are dealt with in a special chapter in an interesting and detailed manner as regards their general characteristics. To the average layman without scientific training few things appear more mysterious and incomprehensible than the estimation of the huge numbers employed in obtaining various scientific data, whether of stellar distances, geological ages, or what not, and there is often a not unnatural tendency to regard them as mere guess-work. The clear and detailed account of the manner in which the enumeration of the corpuscles in the blood is made in Mr. Evans's chapter on the microscope may help to bring conviction to many that not only these but other and very different calculations are really based on sound principles. The uses of the microscope in medicine and the various points concerning which information can be obtained thereby as to the state of the human body are excellently set out. The wisdom of first describing the general principles of immunity before touching on such debated matters as antitoxin, vaccination, and so on, is to be highly commended. A comprehension of these principles will overcome a large part of the *a priori* prejudice with which a lay reader would otherwise approach a subject on which he had already taken sides without any adequate knowledge of the principles involved. The public is well accustomed to the use of diagnostic instruments and appliances, but it is safe to say that there are few who have any conception of why these instruments tell the physician what he seeks to ascertain. A lucid description, therefore, of the principles underlying percussion, auscultation, the use of the thermometer in medicine, the ophthalmoscope, and other instruments, will throw light upon much that is obscure to the public mind. The story of the discovery of anæsthesia is admirably told, and there will be general agreement with the statement that "of all the many blessings which the medicine of modern times has conferred on the human race, none can compare with antiseptic surgery." The wonders of modern surgery following upon Lister's discovery are exemplified in the surgery of the brain, heart, and abdomen, skin grafting, the replacing and transplantation of organs, cosmetic surgery, and the wiring of broken bones. After a judicious middle view in relation to the place of drugs and animal organs in the modern art of healing, Mr. Evans humorously pillories some of the absurd stories whereby the method of discovery of "patent medicines" is heralded. He is of the opinion that it is idle, even if it were desirable, to attempt to prohibit the sale of so-called patent medicines, but he maintains, and we think rightly, that they would be shorn of most of their dangers if it were made compulsory that every such article should bear on its bottle or box a correct statement of its constitutents, for "when the purchaser knew what he was buying he would not be deluded by the charm of the unknown."

The application to public medicine of what has been learned of the principles and methods of modern medicine is admirably illustrated in the chapter on the Political Importance of Malaria, wherein the effect of this and other diseases on the rise and fall of nations is displayed, special reference being made to the observation and research of Sir Ronald Ross and Mr. W. H. S. Jones. The successful fight against malaria and yellow fever in Panama and the West Indies offers a splendid object-lesson for those whose practice it is, without knowing whereof they talk, to depreciate medical science. Industrial diseases are an increasingly important question in these days, and the more widely some knowledge about them is disseminated the better. The same applies to the subject of legal medicine, for a sustained confidence in our judicial processes will be fostered in medico-legal cases by a knowledge of how it is possible in certain legal cases to give those precise statements which are so often a cause of wonder.

Of the medicine of the future the author is optimistic, believing that many of our difficulties will be cleared away and many of our hardest problems solved. The most encouraging thing of all here is the universality of medical progress. To every country medicine has been and is being indebted, and in our own time we have seen Japan, almost fresh from barbarism, come to the forefront in extending the ever-widening boundaries of our science. A broader and more accurate conception of medical problems, a juster appreciation of medical efforts, and by consequence a more intelligent support for enlightened public action, will make possible not only the coöperation of all within the State, but the coöperation of States one with another in the defeat of disease and the victory of health.

Outlines of Biology. By P. CHALMERS MITCHELL, F.R.S., Secretary to the Zoological Society. Revised and Supplemented by GEO. P. MUDGE, F.Z.S., Lecturer on Biology, London Hospital Medical College. Third edition. With 11 plates and numerous diagrams. London: Methuen and Co., Limited. 1911. Pp. 348. Price 6s. net.

THESE "Outlines of Biology" were first published in 1894, and they have been revised and supplemented so that they now cover the ground of the student working for the First Examination of the Conjoint Board of the Royal Colleges of Physicians and Surgeons. It is a work written to meet the requirements of an examining board, though it is claimed that it meets in large measure the requirements of other examinations. It is always a question whether this is the best principle to guide the writer of a text-book. Several of the chapters in previous editions have been supplemented or rewritten and amplified, while chapters dealing with ciliated protozoa, sporozoa, the gross morphology of dicotyledonous plants, the structure of the stem, leaf, and

root, have been added. In addition, an attempt has been made to present the chief elementary facts in the histology of simple tissues. Forty pages are devoted to this subject. Amongst the subjects dealt with, besides those already mentioned, are protoplasm, unicellular plants, yeast, bacteria, protococcus and spirogyra, unicellular animals—e.g., amœba, and ciliated protozoa such as vorticella and paramecium. Attention is next devoted to the botanical subjects already mentioned. A short account is given of animal cells and metazoa—e.g., hydra,—the gastrula and cœlomata—e.g., the earthworm. A comparison between invertebrates and vertebrates forms a short chapter, and then follows a full account of the dog-fish and the frog. Mitosis, maturation of the germ cells, and development of organisms complete the text (pp. 311–327). It will be seen that the scope is limited, but so is the syllabus of the Conjoint Board.

If Mr. Mudge has an opportunity of preparing another edition of this work we hope that he will attend to some mistakes which he has allowed to creep into the third edition. In dealing with the action of the yeast plant it might be well to indicate that the alcohol formed is the ethylic form. On p. 20 "Schultze's solutions" should be defined. The composition is mentioned later. Spores are described as having "exceedingly thick" walls. This is apt to be misleading unless measurements are given. The description of the sympathetic system in the frog might easily be improved. In the chapter on Histology the fat-stream through the thoracic duct seems to have been omitted, while the term "reduced hæmoglobin" had better be discarded and called simply "hæmoglobin." That hæmocyanine contains copper instead of iron might be mentioned. A neophyte in biology is not likely to make much of "clasmatocytes"; their name has nothing to do with extensive vacuolation. It is not necessary to immerse a bone for several weeks in a dilute acid to decalcify it. Does a calcined bone upon the slightest touch crumble into dust? Does bone "consist of a meshwork of living bone-corpuscles with the spaces of the mesh filled up with calcareous salts deposited in an organic base"? and does the blood-plasma exude through the capillaries of the Haversian systems of bone? The sarcolemma of striped muscle is said to be difficult of demonstration. Surely this is not the case. In speaking of the structure of nerves it is stated that "each nerve fibre or axis cylinder is enclosed in two sheaths."

These "Outlines" have for many years thoroughly met the purpose which inspired their production; granted that when the student had mastered the whole of the contents he had not gained a very broad outlook on either the vegetable or the animal kingdom, he had certainly prepared himself for further biological work, in case his attention should not be for the future taken up by his professional studies. We have been a little insistent upon the points where revision is needed, because we consider that it would be a great pity to allow the work to lose credit in any way. The illustrations have been largely added to, and 11 half-tone plates—some with several figures—have also been added.

Pleurisy, including Empyema and Bronchiectatic Conditions. By ALEXANDER JAMES, M.D. Edin., F.R.C.P. Edin., Consulting Physician to the Edinburgh Royal Infirmary and to the Edinburgh City Hospital. With illustrations. London and Edinburgh: Oliver and Boyd. 1911. Pp. 243. Price 6*s.* 6*d.* net.

IN this monograph the various forms of pleurisy are considered chiefly from a clinical standpoint, but with special reference to etiological considerations. The work embodies Dr. James's own experience of the disease, and it is from the standpoint of the practical physician that he presents his views. He quotes illustrative cases to bring out more clearly the general types of the condition which he recognises and to give point to the explanations which he offers of some of its manifestations. At the same time he is careful to state the views of other authorities and to give due weight to them. In regard to the causation of disease, while he recognises that micro-organisms play an important part, he is of opinion that this has been much exaggerated, and he attaches far more importance to the investigation of the conditions which enable them to invade the tissue and produce their effects. In other words, he endeavours to investigate the conditions leading to predisposition, susceptibility, and diminished resistance to disease.

The author describes the symptoms and physical signs of pleurisy in all its forms, and in each instance discusses the mechanisms by which they are produced. The area of dulness occurring alongside the vertebral column on the unaffected side in pleural effusion, to which the name of Grocco's triangle is often applied, is regarded by him as due to the slightly collapsed condition occurring in the lung on that side resulting from the diminished elastic traction of the affected lung. Pleurisy associated with new growth of the pleura is discussed and illustrated by descriptions of cases. The subject of empyema is considered in detail, and separate chapters are devoted to a description of the natural methods of cure, the relation of empyema to bronchiectatic conditions, empyema in unusual situations, fœtid and gangrenous effusions, pulsating empyema, and empyema associated with pulmonary tuberculosis, which is called "phthisical" empyema. We must confess to an even greater objection to the adjective than to the noun from which it is derived. Dr. James inveighs strongly against the tendency to "imbue the public mind with the idea that an individual with tubercular disease who observes cleanliness himself and who lives among people who do the same is a source of danger to his neighbours." This he characterises as being as false as it is cruel, a view with which we are in complete accord. A separate chapter is devoted to descriptions of streptothrix and leptothrix empyemas, and the concluding chapter deals with the treatment of pleurisy and empyemas.

Dr. James's book, while not attempting to record much that is new or original, is characterised by common-sense recommendations, and affords a readable account of the conditions of which it treats.

Ticks: A Monograph of the Ixodoidea. Part II.: Ixodidæ and Bibliography. By G. F. NUTTALL, F.R.S., C. WARBURTON, M.A., W. F. COOPER, B.A., and L. E. ROBINSON, A.R.C.S. Cambridge University Press. 1911. Part II., 348 pp., 4 plates, and 192 figures in the text; Bibliography 68 pp. 12*s.* net each part.

THE importance of ticks as carriers of disease amply justifies a detailed account of these animals, which has naturally also a very large value as a contribution to systematic zoology. The authors are therefore to be thanked and congratulated upon the successful accomplishment of their very great labour. Inasmuch as the bibliography alone contains just over 2000 titles the mere book-work connected with this undertaking must have been of itself an enormous task. When we consider the careful identification of the several species, and the long journeys to museums abroad to see and compare specimens, our gratitude to these authors should be given in no unstinted measure. Nor have they failed to render the results of their labours legible to any instructed zoologists who shall come after them. For the different species are not only clearly and fully described, but their principal anatomical characters are illustrated by as plain and intelligible outline sketches as we remember to have seen in any work of this kind. The bibliography is printed

upon one side of the paper only, which, together with the inclusion at the end of several blank pages, will allow the student of this group of arthropods to fill in the titles of fresh memoirs as they make their appearance. Moreover, the bibliography is more than a mere record of references. In many cases some brief notion is given of the contents of the paper quoted; this will save much time to those who come after.

Hygiene and Public Health. By Sir ARTHUR WHITELEGGE, K.C.B., M.D. Lond., and Sir GEORGE NEWMAN, M.D. Edin. Twelfth edition, revised throughout. London: Cassell and Co. Pp. 760. Price 8*s.* 6*d.* net.

THE issue of a new and revised edition of "Whitelegge and Newman" deserves a special word of welcome. The popularity of this manual results, to a large extent, from the successful manner in which the authors cover the field of "hygiene" in a book of such moderate size and price. Both authors are especially qualified for the task of selecting essential material, from experience in teaching and examining, from their long and close association with local sanitary administration, and from their present position as heads of their respective services in Government departments. Every few years many alterations and additions become necessary in a work of this sort, for besides the growth of our knowledge of the etiology of disease and of the conditions of its progress and prevention, an ever-widening sphere of influence in the State is opening up before the worker in preventive medicine. Even in the few months which have elapsed since this edition was revised, pulmonary tuberculosis has been made generally notifiable, and a million and a half has been voted by Parliament for sanatoriums, thus opening a new chapter of work on the details of which it will soon be essential for the supervisors of public health to be fully instructed.

The present volume has been considerably enlarged, but retains the general form, systematic arrangement, and clearness of exposition which characterised its predecessors. The recent developments of school hygiene are well set out, including the latest circulars of the Board of Education on the subject, and similarly with the Housing Acts and the duties of medical officers of health as recently formulated by the Local Government Board. The results of modern work on the effect of storage in the purification of water, the parasites of meat, the ventilation of sewers and house drains, and numerous other matters have been incorporated, and the chapters on epidemic and infectious diseases have been brought to date in many respects.

The edition will be almost indispensable to the practising medical officer of health, and is also cordially to be commended to the student and to the general practitioner, who so often needs quickly to obtain information from authoritative sources respecting the functions of the central and local public health departments in regard to preventable disease, and to become acquainted with the increasing number of ways in which public health measures are being brought to bear upon the problems which he meets with in his daily work.

Formulaire des Agents Physiques. By Dr. J. LARAT, Dr. G. DAGRON, Dr. RAY-DURAND FARDEL, and Dr. DUBOIS. With a Preface by Dr. G. DIEULAFOY. Paris: Octave Doin et Fils. 1912. Pp. 451. Price 6 francs.

IN this volume a general account is given of the principles and practice of hydrology, hydrotherapy, massage, and the application of electricity in treatment. In the first portion of the work an attempt is made to bring these measures within the scope of general practitioners. It is pointed out that in large cities establishments exist where such procedures can be carried out by especially prepared appliances, but in country practice such is not the case, and hence the instructions given in this work may prove of value. With regard to massage, instructions are given which the practitioner can have carried out, or he can follow them personally in cases where he chooses to afford the time. Various hydrotherapeutic measures are described which can certainly be made use of with very simple apparatus. Electrical appliances in ordinary practice must, of course, be strictly limited, but some useful hints are given which can be easily followed. The use of mineral baths and waters can only partially be imitated, and the best effects are produced by sending patients to suitable spas.

In the second part of the volume diseases are considered in alphabetical order, and the various physical agents that may be employed are discussed under each malady. For instance, under the heading of Dyspepsia, the particular form in which electricity may be applied is first described, then the mineral waters and spas which are of service, and finally the advantages of massage.

As a work of reference this volume should prove of value, for it contains a large amount of information which is generally only found scattered through various text-books.

LIBRARY TABLE.

The Illustrated Medical Dictionary: A New and Complete Dictionary of the Terms used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, &c., with the Pronunciation, Derivation, and Definition, including much Collateral Information of an Encyclopædic Character. By W. A. NEWMAN DORLAND, A.M., M.D. Sixth edition, revised and enlarged. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 986. Price 19*s.* net, or 21*s.* with thumb index.

The Pocket Medical Dictionary. Edited by W. A. NEWMAN DORLAND, A.M., M.D. Seventh edition, revised and enlarged. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 643. Price 5*s.* net, or with thumb index 6*s.* net.

A Pocket Medical Dictionary. By GEORGE M. GOULD, A.M., M.D. Sixth edition, revised and enlarged. 34,000 words. London: H. K. Lewis. 1911. Pp. 1005. Price 5*s.* net.

All these dictionaries are now widely known. The rapidity with which new editions follow one another is a testimony not only to their popularity and usefulness, but also to the desire of their authors to keep them fully abreast of the rapid progress of word-making—very much of it unnecessary, it must be admitted, and some of it certainly philologically monstrous. The medical profession is properly severe on medical quackery, but it is itself one of the worst of sinners as regards philological quackery. There is no reason why every medical writer should think himself perfectly competent to invent not only new terms for new things, but even better names for those things that have already been named. But since he will persist in so sinning, it is necessary that the unfortunate reader should have some guide to explain these new words, and this is even more necessary in regard to the monstrosities than to those terms that are regularly formed on sound philological principles, and consequently are more self-explanatory to medical men of adequate education. It would be easy to find much in this regard to criticise in each of these dictionaries, but until the medical profession consents to submit its proposed new terms to a committee of philological experts to ensure that they shall be correctly framed and shall really convey what they are intended to convey it is useless to find fault.

The sixth edition of Dorland's Illustrated Medical Dictionary is said to be "new from cover to cover," and it

certainly contains many new and useful features, among which may be named the spelling of title words with an initial small letter, the reserving of the use of capitals for proper names, the introduction of biographic information—i.e., the full name, nationality, specialty, and dates of birth and death—concerning men whose names are given to diseases, structures, and procedures, as well as the insertion in their proper alphabetical order in the dictionary of short sketches of the "fathers" of medicine, such as Hippocrates, Galen, Soranus—an addition which, we feel sure, will be welcomed by many; the full definition of terms used in dentistry and veterinary medicine; and, finally, a posological and therapeutical table. The two pocket dictionaries are essentially readers' dictionaries, intended to lie handy for reference while perusing medical literature. Dorland's Pocket Medical Dictionary is so compact as to be readily kept at hand and so reasonable in price as to be within everyone's capacity to buy. In our review of the sixth edition we pointed out that the term "Charcot's disease" is usually applied to the synovial destruction in locomotor ataxia and not to insular sclerosis. In the present edition we find "Charcot's disease" defined simply as "multiple cerebro-spinal sclerosis." Gould's Pocket Dictionary is somewhat fuller on this subject, giving "(1) Amyotrophic lateral sclerosis; (2) arthropathy of tabes dorsalis; (3) multiple cerebro-spinal sclerosis." A careful comparison of the two dictionaries by actual practical use shows, as might be expected, that sometimes one, sometimes the other, seems to be more satisfying. The thinness of the paper in Gould's dictionary, adopted to allow of an increase of contents without increasing the bulk, imports a great disadvantage in the matter of turning over the pages. We doubt if even the enormous content of 34,000 words is sufficient to compensate for this irritating defect, which should be obviated in future editions, even though the bulk be slightly increased or the contents condensed.

All the books can be recommended.

Sanatoria for the People. By CHARLES H. GARLAND and THOMAS D. LISTER, M.D. Lond. London: The Scientific Press, Limited. 1911. Pp. 71. Price 1*s.*—In this small volume a good popular explanation is given of what a sanatorium is, "what work it performs, what work it is capable of performing, and in what relation it stands to the other methods of dealing with consumption." The writers take the stand that the sanatorium is the most important link in a chain of measures by which pulmonary tuberculosis could be so diminished that a bright prospect would be offered of its eventual eradication. They quite rightly point out, however, that although such an important one it is only a link, and in order that it may reach its maximum of efficiency it must be supported by the other necessary links. It is necessary that this should be plainly realised by the general public, otherwise with the establishment of the proposed State sanatoriums equally important preventive measures may be neglected. There are a good many useful hints given in the course of the book. For instance, it is stated that the sanatorium, *per se*, should be confined to the treatment of early cases in which there is a reasonable prospect of the arrest of the disease. There has been a tendency to adopt the idea that because a patient has pulmonary tuberculosis, no matter what the stage of the disease, *ergo*, he must go to a sanatorium. Such a conception of the purposes of a sanatorium cannot fail to engender want of confidence in a most valuable therapeutic measure. The authors also lay stress on the importance of differentiating between a sanatorium and a "home of rest." The former must be represented not only as an institution for the treatment of tuberculosis, but also as a school of hygienic living at which the patient will be taught not only how to live healthily, but also how to perform his work healthily. This book will help the non-medical community to a more accurate knowledge of the nature and scope of sanatorium treatment and thus aid in "the State campaign against consumption."

The British Red Cross Society Training Manual, No. 3, by JAMES CANTLIE, M.A., M.B. Aberd., F.R.C.S. Eng., V.D. London: Cassell and Co., Limited. 1911. Pp. 226. Price 1*s.* net, post free 1*s.* 2*d.*

Red Cross Manual of First Aid and Stretcher Drill for Red Cross Students, by D. M. MACDONALD, M.D Aberd., medical officer of health, Leven, Fife, and examiner to the St. Andrew's Ambulance Association. London: George Gill and Sons. 1911. Price 1*s.* net.

First Aid to the Injured and Sick: An Advanced Ambulance Handbook. By F. J. WARWICK, B.A., M.B. Cantab., M.R.C.S., L.S.A., and A. C. TUNSTALL, M.D., C.M., F.R.C.S. Seventh edition, revised. 60th thousand. Bristol: John Wright and Sons. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1911. Pp. 246. Price, paper, 1*s.* net; leather, 2*s.* 6*d.* net.

Mr. Cantlie's book is intended to guide those who have already acquired a knowledge of first aid and nursing to act collectively in carrying out the Red Cross work, to accustom them to discipline, by which alone efficient service can be rendered, and to stimulate them to exercise their initiative and resourcefulness in constructing and applying improvised means of providing help, shelter, and transport for the sick and wounded in emergencies. It has a semi-military character and is issued with the approval of the War Office. The improvising of camp kitchens, latrines and beds, camp cooking, and many other things connected with outdoor life will render it of even wider service than its original aim sought.

The *Red Cross Manual* of Dr. Macdonald is a compromise between the more technical and the elementary aspects of ambulance work and first aid, covering all the ground necessary for Red Cross work and embodying squad and stretcher drill. The book is divided into 12 chapters, at the beginning of each of which a few notes are suggested for the use of the lecturer, and at the end some questions are inserted for the student. The arrangement will commend it to both teacher and student.

First Aid to the Injured and Sick, the advanced ambulance handbook by Dr. F. J. WARWICK and Dr. A. C. TUNSTALL (both of the Royal Army Medical Corps T.F.), is now in its seventh edition. It has been thoroughly revised and the new stretcher drill has been incorporated from the Royal Army Medical Corps Training, 1911. The book fully sustains its previous reputation.

My Life Story. By EMILY, Shareefa of Wazan. Illustrated. London: Edward Arnold. 1911. 8vo. Pp. 327. Price 12*s.* 6*d.* net.—This book possesses a quality that is rare nowadays—it is the simple direct impressions of a writer who has "been there" and stayed there, and lived the life of the people. The book is so simple and so modest in style that the authoress writes as though everyone knew something of Morocco. She hardly gives any indication as to the position of a shareef, and none as to that of Wazan, yet to describe herself as Shareefa of Wazan should be as good an introduction as (say) the style of Duchess of Norfolk, and the former is in antiquity and national influence far the superior title.

Everyone now ought to know something about Morocco, if only from reading the newspapers. But, also, it is easy to get a cursory glimpse at the Atlantic coast ports even within the limits of a three weeks' cruise. Morocco is far more oriental than many countries lying further east, and

may be a recognised resort for travellers of moderate means and leisure as long as its national character persists. The sherifs, or shareefs (the English spelling is optional), of Wazan are hereditary chieftains of great importance in northern Morocco. The word sherif implies a direct descendant from the Prophet, and the sherifs of Morocco are the offspring of Imaum Mahanmal (the fifth descendant of Fatima), whose son Idris fled from Mecca to Tangier in 786 A.D. The sherifs have not always occupied the Sultan's throne; the direct descendants of Idris reigned till 986. After that there were no reigning sherifs till 1544, when the line of Hazan ruled for a century and the Filalie sherifs ever since; to the latter family Mulai Hafid, the present Sultan, belongs. Most of the dominant families in Morocco claim descent from the Prophet, and into such a family an English girl married nearly forty years ago and has remained there, and entered fully into native life, surrounded entirely by native servants and retainers. The results of her experience are set down in this volume, and the simplicity and unaffected *naiveté* of the writing give the record an aspect of entire trustworthiness. The Shareefa led a very retired domestic existence, though overcrowded with difficulties and even dangers to her life. Any foreigner residing in the household of a rich noble in Morocco would be so exposed, even if he or she were a Mohammedan convert; but the Shareefa remained a Christian, and those who know the rigid fanaticism of the country know what dangers and difficulties that implies. Readers must not expect any political information from this volume, or any light upon recent history in Morocco, but, on the other hand, there is a wealth of interesting details about domestic habits, the care of children, the customs of marriage, the ritual of burial, and other matters which only a long and intimate residence could afford to a writer. There is an appendix telling of quaint sayings and superstitions among the Moors. For instance, "Children under two months old must not have their laundry out of doors after 3 P.M., otherwise they will cry all night." This is a sample, and there is a whole liturgy of portents attached to itching in various parts of the body. It is to be hoped that the Shareefa will make further contributions to the literature about Morocco, a literature which is at present very scanty in English and not abundant in any language. The way to a hearty welcome is paved by this very genuine and interesting volume of impressions.

Wright's Improved Physicians' and Surgeons' and Consultants' Visiting List. Compiled by ROBERT SIMPSON, L.R.C.P., L.R.C.S. 1912. Nineteenth edition. Bristol: John Wright and Sons, Limited. Price 5*s.* to 7*s.*—This well-known visiting list contains besides the usual information a visiting list ruled for a month on the open page, to accommodate from 40 to 240 patients, at prices ranging from 5*s.* to 7*s.*, a consultant's record showing the patient, medical attendant, and consultation engagement, obstetric engagements, vaccination engagements, notification of infectious diseases, nurses' addresses, patients' special addresses, motor expenses (a new feature). A perpetual list is also published (Form B), the same in its contents as Form A, but arranged to be commenced at any time and used until filled.

JOURNALS AND MAGAZINES.

The Medical Chronicle.—By way of original matter there is published in the January number of this magazine a thesis by Dr. James Randal Hutchinson on the Presence of Typhoid Bacilli in the Stools and Urine during Enteric Fever and Afterwards. The author concludes that 2 per cent. of such patients become chronic carriers of bacilli, while 8·3 per cent. are still excreting the organisms at or about the time of their discharge from hospital. These figures are based on a study of 50 patients, a number scarcely large enough to give accurate percentage results, but the general conclusions reached are of considerable importance.

The Birmingham Medical Review.—The opening number of this journal for this year is considerably bulkier than those to which we have been accustomed, its increased size being partly due to the thicker paper employed. In it Mr. Leonard Gamgee discusses the Differential Diagnosis of Tumours of the Pylorus, and Dr. R. Beatson Hird deals with Ophthalmic School Clinics, noting that more than one "dunce" has been cured by a pair of spectacles. Dr. Jameson Evans writes on Pituitary Growths, distinguishing the symptoms due respectively to excess and defect of pituitary secretion, the former including acromegaly and gigantism, and the latter some forms of infantilism and "certain cases in which there is excessive development of fat with mental and physical torpor, and disturbance of sexual function—dystrophiæ adiposo-genitalis of Fröhlich."

West London Medical Journal.—In the January issue is published an interesting paper by Mr. N. Bishop Harman on the Comparative Anatomy and Development of the Muscles of the Eye. He notes that the ocular muscles are developed from those of the first gill cleft, and explains on this principle that curious phenomenon known as "jaw-winking," and also certain clinical cases in which paralysis of the ocular muscles is accompanied by weakness of the orbicularis. Dr. Seymour Taylor writes on Unrecognised Diphtheria, and Dr. T. Grainger Stewart on four cases of Spinal Syphilis.

ERRATUM.—In our review of *Analyse des Harns* on Jan. 20th, p. 172, it was stated that "the reference for the account of Moore's test for sugar in the urine is given to the article in THE LANCET of Sept. 26th, 1844." This reference is not quite correct. The article on "Liquor Potassæ: A Test for Sugar in the Urine; by John Moore, Esq., one of the Resident Medical Officers of the Queen's Hospital, Birmingham," appeared in THE LANCET of Sept. 14th, 1844, p. 751. The author's account of the origin of the test is as follows: "That liquor potassæ when boiled with diabetic urine produces a characteristic colour was first noticed by my friend Mr. Palmer, Dispenser to the Queen's Hospital. This led him, with myself, to consider that it might be made practically useful, and induced us conjointly to institute the following experiments."

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

DRY DIAMALT.

(THE BRITISH DIAMALT CO., 11 AND 13, SOUTHWARK-STREET, LONDON, S.E.)

WE have previously examined the malt products of this company and have reported upon their high digestive activity. Those were concentrated preparations in the shape of thick fluids. We have recently had submitted to us a sample of dry diamalt malt extract. This is an attractive-looking preparation, a crisp light-brown powder. In spite of the drying process through which it has been put its activity on starch is remarkable. We found that in one hour at body temperature one part by weight of dry diamalt completely converted five times its weight of starch, while in two hours one part of dry diamalt digested no less than 20 times its weight of starch. The powder dissolves readily in water and has a peculiarly attractive malty flavour. It contains of course all the constituents of malt soluble in water—viz., malt, sugar, protein, and phosphates. The moisture amounted to 2·50 per cent., the protein to 7·93 per cent., and the mineral matter to 1·50 per cent. The figure for protein is the highest we

have found in a malt extract. Its convenience for use, as compared with the sticky extracts, is obvious.

COLLOSOL SILVER AND COLLOSOL MERCURY.

(MESSRS. OPPENHEIMER AND CO., LIMITED, 179, QUEEN VICTORIA-STREET, LONDON, E.C.)

From the point of view of the colloidal state these interesting preparations are quite satisfactory. Further, they are reported to be stable, the ultramicroscopic examination showing the characteristic appearance of a metallic solution. On heating them, also, no change is shown, and when cooled there was no difference. On evaporation the residue obtained was easily taken up again except a very small scum, but there was no suggestion of metal being thrown out. On dialysis the absence of reduced salts was demonstrated. We understand that experiments have shown that the metals present exercise a sufficient antiseptic influence to preserve the colloidal agent in the solution. These preparations are excellent types of the respective metals in a satisfactory colloidal state. An interesting letter appears in another column in regard to their clinical value.

JOHA (SALVARSAN).

(S. MAW, SON, AND SONS, 7–12, ALDERSGATE-STREET, LONDON, E.C.)

Joha is described as a 40 per cent. preparation of salvarsan ready for immediate use. We find that it is an oil suspension of the organic arsenic compound. The oil is iodipin, which is readily absorbed. Some importance is attached to the use of this oil and to the preparation of joha in general, inasmuch as it is said that it causes no pain when injected into the right place and produces no infiltration. The percentage of salvarsan is high, so that large quantities may be introduced by using relatively small volumes of joha. Joha is stated to keep well. Its composition is due to Dr. Carl Schindler, Berlin, and Dr. A. Neisser, Breslau, who emphasise the importance of using the special syringe designed by the former physician, which appears to us to offer decided advantages.

JAEGER SARDINES.

(THE JAEGER-SMEDSVIK CO., CHESTERFIELD HOUSE, 98, GREAT TOWER-STREET, LONDON, E.C.)

We have examined these sardines, which are of a particularly small type. The tin showed no sign of corrosion, and neither the oil nor the fishes showed any metallic contamination. The oil is correctly described as olive oil. The tins are solderless. The sardines had the peculiar appetising flavour characteristic of the good fish, which in oil is a very nutritious dainty.

POULTOGEN.

(THE POULTOGEN CO., 28, MARKET-STREET, MANCHESTER.)

Poultogen is a poultice made on lines indicated by modern practice. It consists of a stiff putty-coloured paste containing antiseptics, amongst which we recognised oil of wintergreen, boric and salicylic acids, an organic iodine compound, and pine oils. The powder basis is calcined silicious earth, the whole being amalgamated with the aid of anhydrous glycerine. It is obvious, in view of this account of it, that poultogen is both antiseptic and hygroscopic, two very important qualities of a poultice. Further, it has the property of retaining heat for a relatively long time. It is an excellent application when moist heat is required continuously.

THIOCOL.

(THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LIMITED, 7 AND 8, IDOL-LANE, LONDON, E.C.)

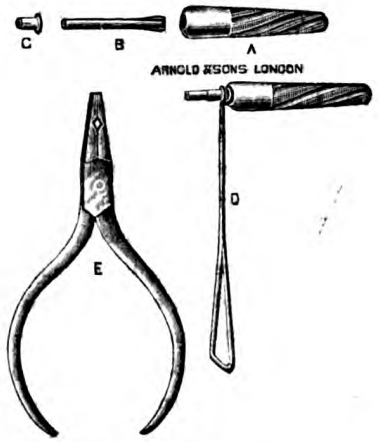
We have already reported upon thiocol, which is a convenient and active soluble guaiacol preparation. The tablets are now issued without the word "thiocol" stamped upon them, as it had been pointed out to the manufacturers that such stamping was sometimes inconvenient. Thiocol serves the purpose of a soluble creasote, and favourable accounts are given of it, chiefly in the treatment of pulmonary affections.

New Inventions.

A MODIFIED INSTRUMENT FOR THE PERFORMANCE OF THE OPERATION OF SIMPLE TREPHINING FOR THE RELIEF OF GLAUCOMA.

AN experience of over 400 trephinings has shown that many of the instruments for the purpose now on the market are imperfect. The best I have seen is that invented by Mr. Sydney Stephenson, and the guiding lines for the present model have been taken from that instrument. The new features presented are as follows:—

1. *The shape of the handle* (A).—In order to give the surgeon a good grip and to prevent his fingers from constantly slipping down as he presses, (1) the handle is made conical



with the apex of the blunt cone upwards; (2) the fluting is spiral in arrangement; and (3) the edges of the fluting are serrated at right angles to its length.

2. *The nature of the blades* (B).—These are made so that they can be used and thrown away as soon as they become blunt. The blades are made from solid drawn steel tubing. One end of each blade is divided into three parts and opened to form a spring; this when inserted into the handle holds the trephine firmly; the other end forms the cutting blade, and the edge is brought up sharp from the inside. This enables the operator to cut a hole the exact size of the trephine.

3. *The method of fitting the blades.*—A small pair of pincers (E) is supplied, with which the blade can be easily fitted into, or removed from, the handle. This should always be done at the time of operating. The blades must never be left in after use. The handle is hollowed throughout so that it can be easily and quickly cleaned and dried after use by means of a pipe cleaner (the best form being the Metropolitan pipe cleaner made in the United States of America, and sold by all tobacconists.) The bore of the proximal portion of the hollow is slightly less than that of the distal portion. This, whilst enabling the handle to be cleaned, at the same time prevents the blades from passing up more than the correct distance.

4. A stop (C) can be supplied which can be fitted to any of the blades.

5. *A small handle is provided* (D) with a loop at one end, through which the blades can be passed. This enables an operator to keep the cutting edge of his blade in one position during the operation, and is an improvement on the method of holding the blade with forceps.

The whole instrument is supplied in a small case by Messrs. Arnold and Sons, of Giltspur-street, London, E C, to whom I am much indebted for the assistance they have given me in working out the details of the instrument.

R. H. ELLIOT, Lieutenant-Colonel, I.M.S.
Government Ophthalmic Hospital, Madras.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 3, 1912.

The National Insurance Act.

THE week in which we write has been a momentous one for the medical profession as far as our possible relations with the National Insurance Act are concerned. At the end of last week, as is more fully explained in another column, the National Insurance Commissioners invited various medical bodies to meet them at a conference to be held to-day (Friday), Feb. 2nd, to consider matters of procedure in bringing the Act into operation and make suggestions thereon. It was obvious to all the bodies concerned that the time given to them in which to make up their minds whether they would or would not attend the conference was entirely too short; there was no opportunity to consider what their representatives should say, and no chance of inviting the opinion of the different constituencies. It was seen at once that a body which refused to be represented might appear to wear the unfortunate air of being sulky, of being determined to lend no assistance to a group of officials endeavouring to do their best; on the other hand, any institution represented at the conference might be considered to have acquiesced in everything that took place, however impressive the necessary silence preserved by its delegates. (There are at the present moment scores of persons ready to say this sort of thing.) We are extremely glad to learn that on Tuesday afternoon at a Comitia of the Royal College of Physicians of London, it was decided that representatives of the College should not be sent to the conference, and we hope that the same will be the decision arrived at by the Council of the Royal College of Surgeons of England, a meeting of which body took place yesterday (Thursday) afternoon, with results which are not known to us as we go to press. Nor do we know what action will be taken by the General Medical Council. The Council of the British Medical Association have been placed in the same position as the two Royal Colleges by the early date suggested for the conference. A meeting of this Council was held on Wednesday afternoon, when it was eventually decided not to be represented at the conference, a decision which followed inevitably upon the fact that the next meeting of Representatives will not be held until Feb. 20th. The decision of the National Insurance Commissioners to hold this conference without giving proper opportunity to the medical profession of coming to any common decision as to what they might desire to recommend is in our opinion most unfortunate. If the Commissioners, instead of wishing to ascertain what is the collective medical opinion, had designed thoroughly to embarrass the leaders of the profession, they could hardly have taken a more apt course.

The suggestion that a Central Council should be formed by representatives of the great corporations, with a temporary mission to advise and support the profession in the present crisis, has met, we are glad to know, with very general approval, and certainly the circumstances which we have described above point strongly to the valuable work which such a Council might do. The Insurance Commissioners have expressed a desire to know what the views of the Royal Colleges are, and it is essential under the circumstances that the Colleges should be able to take a common line in any advice which they might wish to give to the Commissioners as much as in any support which they might be able to offer to the medical profession—and we may be certain that they will offer this willingly to those whose education has lain largely in their hands. Exactly the same words describes the position of the Society of Apothecaries of London. By far the greater part of the medical profession in England, whatever additional academic degrees they may have acquired, owe their places on the Medical Register to the possession of the Diplomas of the Royal College of Physicians of London, the Royal College of Surgeons of England, or the Society of Apothecaries of London, and the governing bodies of these three corporations cannot but feel that the present position of their diplomates is seriously affected by the medical provisions of the National Insurance Act, and that the *personnel* of their future adherents may be much altered in quantity or lowered in quality if those provisions remain the law of the land. If any such Central Council as has been suggested should come into being, the British Medical Association would probably be happy to assist its efforts and would certainly bring to the combination an element of great strength. It is unlucky that at the present moment the Council of the British Medical Association is to some extent on its trial, for the new advisory body would desire to start free from the factiousness which has so far interfered with the attempts of the medical profession to deal with the Act. But the moment that the British Medical Association is itself as a mass satisfied with its Council it is our opinion that the assistance of that Council should be sought, and that a common line of action should be taken against the existing medical provisions of the Act. Delay, reasonable delay, in the date of coming into operation of the Act should be demanded, during which time the position can be calmly reviewed. So far there is, with a very general dislike of the Act, a determination on the part of many thousands of practitioners not to work under it save with certain detailed safeguards. A successful strike would be deplorable in its public effects; a strike which failed would only be less dreadful in the loss of prestige that would result. A calm consideration of the regulations by a Central Council may avert grave disasters, and for this reasonable time is required.

Personality in Medical Teaching.

A CANDIDATE for the office of assistant physician or assistant surgeon to a great hospital, an office to the holder of which fine opportunities of teaching medicine or surgery to others must in due time be afforded, could perhaps produce no higher recommendation than evidence that, in the capacity of house physician or house surgeon, he had been able to secure a following of students when performing his duties in the wards; or, in other words, that he had rendered these duties interesting and instructive to bystanders, and had prevented them from degenerating into routine. The contemporaries of a great clinical teacher, when their memories go back to the earlier portions of his career, will seldom fail to recall as a characteristic of him that he possessed an exceptional power of directing his own and their attention to matters which at first sight were apparently of only subordinate significance, and of deriving from them important guidance in respect either of diagnosis or of treatment. For example, a whole generation of students at St. Bartholomew's Hospital will remember exactly these things of the late Sir HENRY BUTLIN, whose untimely death is recorded in our columns this week. To the perception of such a teacher few symptoms would be trivial and none would be negligible, while the positive value to be attached to each would only be determined by an analysis of the conditions attending or producing it. The consequent intellectual operations would be performed more rapidly and, so to speak, more instinctively as they became more and more habitual, until a condition might ultimately be attained in which they would seem to onlookers to be intuitive and to depend upon a degree of penetration which the average practitioner could scarcely hope to attain. We should hold, on the contrary, that this swiftness of operation, coupled with inclusiveness and accuracy, was but the due reward of diligence, habitually exercised upon matters which the negligent would have passed over as unworthy of their attention. It is, we believe, the power of grasping such matters which mainly constitutes the difference between the more and the less skilful practitioner, and it is the power of fruitfully directing attention to them which mainly constitutes the special qualification of the really great teacher. The methods of appeal to the senses of the learner may be almost infinitely various, but the principle underlying them is practically always the same. The teacher by example may apply some test which the learner would not at first have supposed to be called for in the conditions manifestly present—such, for instance, as an examination of the urine for albumin or for sugar in a case of defective vision; the Socratic questioner may guide his class to sound conclusions through inquiries which at first sight appear irrelevant; and the born demonstrator may point out the greater or less readiness of the abdominal muscles to assume a condition of protective rigidity, and may draw such inferences from the facts as they will justify. The principle that no discoverable condition should be suffered to escape notice, or should be omitted from consideration in the formation of a reasoned judgment upon the case, as it is that upon which the attainment of accuracy must depend, is also that which it is the first and most important duty of the teacher to inculcate.

The qualities of sense and of intellect which mainly contribute to the complete development of the accomplished clinical instructor are not always those which are of the highest importance to his colleague in the lecture-room, whose work is rather the inculcation of principles than the demonstration of facts, and whose main object should be to clothe those principles in language calculated at once to stamp them upon the memory and to render them clear to the intelligence. A good presence, an impressive manner, an agreeable voice, a perfect intonation, are all of them aids of high importance; but the most important of all is such a knowledge of the English language as may reduce the employment of technicalities to the lowest possible point, and may permit the construction of sentences which, in the terms of COBBETT'S famous description, should be "as clear as a pebbled brook," and "should not only not be liable to be misunderstood, but should not be capable of being misinterpreted." There are only a few now living who can remember how these conditions were fulfilled by those lectures of Sir THOMAS WATSON which furnished a text-book of medicine to two generations of practitioners, and which survive, although the progress of scientific discovery has gone far beyond them, as perpetual examples of the way in which it is possible to express the recondite in language of absolute lucidity, and to distinguish with precision between what is known and what is conjectural. No man who aspires to be a great, or even a good, teacher can take too much pains in the perfecting of his most essential weapon, language, or in the attainment of a power to draw a verbal picture which shall at once satisfy the intellects and impress the memories of his auditors. Nor can he be too careful to swim without corks, and to render it clear that his mastery of his subject needs no reinforcement from notes or references. Most of us have dismal recollection of lecturers at our medical schools, who sat opposite to the class with the head well down, reading aloud in a dreary monotone from the proof sheets of a forthcoming treatise. The true lecturer should lose no opportunity of placing himself *en rapport* with his audience, and he may often do this most successfully by selecting some single member of it, and by pressing his point home until an answering intelligence in the face of the special hearer shows that, in one instance at least, the end desired has been attained. The average student, even if he be not of the highest order of industry or of capacity, is prompt to recognise and to admire knowledge in his teachers; and those who would teach him efficiently should regard as a first duty the fulfilment of his reasonable expectations in this respect. They should make it abundantly manifest, alike in the wards and in the lecture

room, that they have carried their own studies to a point which he is not yet prepared to reach.

DUGALD STEWART once pointed out that the possession of a perfect English style, in which it seemed as if every word used was the only one which could have been selected for that particular place, or to express that particular shade of meaning, was apt to induce the careless reader to suppose that he also could write in a similar manner; and, as all things have the defects of their qualities, it is perhaps conceivable that the best possible lecturing and clinical teaching may sometimes lead the student to underestimate the difficulties of the pursuit in which he is engaged, and to aim at results by shorter roads than those which alone render them attainable. The almost intuitive perception of a thoroughly trained observer may induce a student to strive after rapidity of diagnosis by a hasty glance at the salient, and possibly misleading, features of the case, and in this way to attain nothing but a lamentable facility for jumping from insufficient data to erroneous conclusions—conclusions to which the person so framing them will be only too likely to adhere until it is too late to rectify the consequences of his error. A teacher can hardly be too much upon his guard in striving to protect his pupils against this particular source of error, and in impressing upon them the necessity of neglecting no method of inquiry by which light may possibly be thrown upon any of the conditions of a case which admits of doubt. Under the operation of the new Insurance Act, under whatever shape it may be brought into operation, and under whatever terms medical men may be found who will work according to its provisions, the profession will be confronted with very serious questions concerning the validity of the claims put forward for relief on account of illness, and will in all probability be compelled to take the occurrence of systematic malingering into serious account. It is notorious that the recent enactments for affording compensation for injuries received during employment have definitely lengthened the average time of consequent disablement; and it is not necessary to regard the whole of this effect as a result of deliberate imposture. But, as Mr. FRANK MILTON said in our columns last week, "it is difficult to avoid coming to the conclusion that the benefits to be obtained under the Workmen's Compensation Act have had a distinct tendency towards increasing the number of cases of accident applying for treatment." This increase is partly due, no doubt, merely to the fact that the compensated man is in no hurry to return to his occupation. In the future, however, a large element of malingering is likely to come under the notice of medical men, and to derive importance from the fact that it will be at least as necessary to protect the honest claimant as to expose the dishonest one. The medical and surgical teachers of the near future may not improbably be faced with the new duty of preparing their pupils, in a great number of obscure or doubtful cases, to hold an even balance between the patient and the State; and upon their success in this endeavour will largely depend the success of any system of general insurance against sickness, however sound its financial basis.

Tenure of Office of Medical Officers of Health.

ALTHOUGH the conditions of appointment of medical officers of health in the provinces have been considerably improved by the terms of the General Order of the Local Government Board of Dec. 13th, 1910, they are still far from satisfactory. Until the end of 1910 medical officers of health in England and Wales, except those appointed by the metropolitan borough councils and by county councils, could be, and usually were, appointed by local authorities for limited periods, usually of one year. At the expiration of the period of appointment there was no obligation on the part of the authority to re-appoint, and no intimation was required to be given to the medical officer of health that he would not be re-appointed. The order of Dec. 13th has enabled a local authority to make an appointment without limit of time, in which case the officer appointed holds office until he dies or resigns, or is removed by the electing authority with the consent of the Local Government Board, or is removed by the Board itself, or is proved to be insane. That is to say, his tenure of office is similar to that of a Poor-law district medical officer who resides within his district. The appointment of medical officer of health may, however, still be made for a specified period, but at the expiration of that period the appointment is held on a yearly tenure, the local authority having power to give three months' notice of its termination, provided the notice expires at the same period of the year as that at which the original term expired. The assent of the Local Government Board is not necessary to make this notice a valid one, but in one or two instances, where there does not appear to have been adequate reason for such dismissal, the Board has intimated that it would not be prepared to sanction the appointment of a successor, with a view to the refunding of a moiety of the officer's salary from the Exchequer grants. This course was adopted in the case of the Claypole rural district council, who called upon the medical officer of health, who had held office for some years, to resign for what, in the opinion of the Board, were insufficient reasons. The ratepayers of the district are now, therefore, paying the whole of the salary of the newly appointed medical officer of health. If the Board will continue this policy the position of medical officers of health will be materially improved, though it would be still better if they were placed in the more secure position occupied by all Scottish medical officers of health and by those who hold office in London and under the county councils.

FORTY-FIRST CONGRESS OF THE GERMAN SURGICAL SOCIETY.—This congress will take place from April 10th to 13th, 1912, at Berlin. As the space in the Langenbeckhaus, which has been resorted to on former occasions, has been found too small, the committee of the society has for this year's meeting hired the Beethoven Saal der Philharmonie, Berlin (entrance, 32, Köthener Strasse). The congress will be opened on the first day at 10 A.M., and on the other days the hours of business will be from 9 to 12.30 and from 2 to 4. The president for 1912 is Geh. Med.-Rat. Professor Carl Garrè, of Bonn. Cards of membership and all particulars may be obtained from Herr Melzer, Langenbeckhaus, Ziegelstrasse, 10/11, Berlin, N.24.

Annotations.

"Ne quid nimis."

THE RHODES SCHOLARS AND THEIR CAREERS.

THE annual statement of the Rhodes Trustees—describing the work achieved under the trust in sending scholars to Oxford from the colonies, Germany, and the United States—is already an interesting document now that definite results are beginning to be ascertainable, and the statistics which it contains will increase in importance as time passes. In 20 or 30 years, when the promising young men of to-day are in a position to have their life-work scrutinised, and when the educational antecedents of those who then are occupying leading positions in statecraft and diplomacy, in the professions of science and law, in commerce, or in the world of action and adventure are inquired into and criticised, the dispositions of the will of Cecil Rhodes will come up for judgment after a verdict has been found upon proven facts. At present we are watching the development of the experiment of sending to be educated at Oxford nearly 200 students at a time (there were 176 Rhodes scholars on the books in 1910–11) who, but for the intervention of a great and original minded Englishman, would never have gone there except possibly upon brief visits as more or less intelligent tourists. Up to now they have worked with varying degrees of intellectual distinction, their list of honours during the past 12 months recording but few first classes, seconds and thirds being more conspicuous, numerically. Not the least interesting part of the experiment, it must be remembered in this connexion, is the consideration of physical and athletic excellence as well as of intellectual qualifications imposed by the will of the founder upon those who select the beneficiaries under it. The interest, of course, lies not in studying the athletic performances of Rhodes scholars at Oxford, but in watching the effect of special cultivation upon intellectual plants selected with equal regard for the *corpus sanum* and the *mens sana*, a condition of choice which obviously places some restriction upon merely academic results. At present Rhodes scholars appear by their choice of professions to suggest that the exercise of useful influences may be expected of them rather more than conspicuous intervention in the economy of the world. Out of 250 who had done with Oxford and made their first choice in the matter of professions at the beginning of 1910, 84 had selected educational work, 66 the law, and 19 religious callings. Educational work with the prestige conferred by an Oxford degree opens, no doubt, a tempting path to immediate independence, and both the law and education are careers which may be abandoned, or which lead to high distinction within their own limits, but the numbers given above leave but a restricted number for entry into science, medicine, engineering, the civil service, diplomacy, commerce, and the other avenues of distinction open to a class of picked youths who have enjoyed exceptional educational advantages. In the future of those who enter the medical profession we naturally take a keen interest. There are 11 of these among the 250 to whom reference has been made, and we look forward to seeing the proportion increased, to the advantage of the medical profession and its patients, using these terms in their widest sense. Science recognises no territorial limitations, and the bond of a common struggle against disease and human suffering will be strengthened by early friendships and by the sympathetic comradeship of men working thousands of miles apart who have drawn their first instruction from the same source and inherited the same honourable traditions.

THE CAMPAIGN AGAINST TUBERCULOSIS IN ITALY.

WE have received a copy of the journal *La Tubercolosi* for November–December, which is published monthly at Rome as the official journal of the organising committee of the Seventh International Congress against Tuberculosis meeting at Rome from April 14th to the 20th of this year. The subject-matter is printed in Italian, French, German, and English. Forms of application for membership of the Congress, and information in regard to reduction in rates of travel to the Congress, are included with this number. There is also an interesting *résumé* of the measures in force and those in preparation to combat tuberculous disease in various parts of Italy. It would appear that hitherto more attention has been paid to general hygienic reforms and to the moral and economic elevation of the working classes than to the actual provision of sanatoriums. In general these reforms may be summed up as endeavours to raise wages, the provision of insurance against accidents, and of legislation against diseases caused by conditions of labour, and measures to secure better housing. Concessions are granted by the Italian Legislature to certain coöperative societies, mutual benefit societies, charitable institutions, corporate bodies, and local authorities to further cheap and satisfactory housing. Regulations are in force for the construction and sale of such buildings and for the expropriation of areas for hygienic reasons. Facilities for loans are also offered. Recently a new board has been constituted in many Italian cities called the Independent Board for the Cheap Housing of the People. It is supported by contributions from municipal bodies, the savings banks, benefit and loan societies, and from other societies and private individuals. The provision of sanatoriums is also being actively pushed forward, and a list of these, with a brief description of their scope and accommodation, is included in the article to which we refer. Various tuberculosis dispensaries, modelled on those now general in most countries, have been started, and are engaged in the prophylaxis and treatment of the disease. A central alliance of all the agencies at work has recently been inaugurated by Professor Guido Baccelli, Professor Rossi-Doria, and Professor Tamburini. Its objects are the coördination of the various societies and agencies at present engaged in the work of combat against tuberculous disease and to awake public interest in the subject. We have read the article with interest, as it shows that the Italians are fully aware of the importance of this subject to the national welfare, and are actively engaged in work with this object in view. The session of the Congress should serve a useful purpose in directing public attention to these matters and in aiding the authorities in their work.

SALT IN POTABLE WATERS.

THE amount of sodium chloride found in potable waters rarely exceeds 5 grains per gallon, but there are certain exceptions, the most notable of which are in the county of Essex, where the water derived from the Thanet sand and from the chalk below contains considerable quantities, not only of salt, but of sodium carbonate. Over a large area the salt averages 50 grains per gallon and the sodium carbonate 20 grains, and over a more limited area the salt increases to 80 grains and upwards per gallon. The sodium carbonate, however, does not increase in the same proportion. The origin of these saline constituents has given rise to much speculation amongst chemists and geologists, but it is accounted for by the researches of Dr. J. C. Thresh, county medical officer of Essex, who, in an article which is published on p. 315, shows that they are derived from an admixture of sea water and chalk water altered by percolation through

the Thanet sand. The sodium chloride derived from the sea water remains unchanged, whilst the calcium carbonate of the chalk water is converted into sodium carbonate. That thousands of persons near London use for drinking and all domestic purposes a water containing over 50 grains of salt per gallon will cause general surprise, but Dr. Thresh's studies of the sickness statistics of the districts in question show that they are amongst the healthiest in the county, and as the county mortality rates are generally the lowest, or very nearly the lowest, of all the counties in England and Wales, it is clear that the use of such water has no appreciable effect upon the health of those who habitually drink it. During the last few years the difficulties experienced in obtaining water-supplies for large villages in the north-east portion of the county of Essex have raised the question whether a water of the above character containing 80 grains of salt per gallon will be objectionable for domestic purposes. Farms and cottages dotted over the area are supplied with such water from deep wells, and strangers, after getting accustomed to the flavour, do not object to it, while all who use it consider it to be perfectly wholesome. The only available sources of supply for the villages referred to appear to yield water of this character, and Dr. Thresh has been compelled to express an opinion and has decided that the water is wholesome and may be used with impunity. His opinion is based exclusively upon his Essex experience, no other being apparently available. At various times scurvy and other diseases have been attributed to the excessive consumption of salted food, and in the *Indian Medical Record*, April, 1911, a list is given of the evils arising from "undue salt eating," but there is no definition of an undue amount. There is no doubt from the experience in Essex that 50 grains of salt per gallon of water is perfectly harmless, and some evidence that even much larger amounts have no ill-effects, but it is desirable that this evidence should be further supported before expending thousands of pounds upon works to supply whole communities with waters of this character.

THE PROPAGATION OF PLAGUE WITHOUT THE AID OF INFECTED RATS.

WE have received from Dr. Choksy, of Bombay, a well-known authority on plague, a letter, which appears on another page, adverting to an article published in THE LANCET of Dec. 16th, 1911, p. 1714, entitled, "The Propagation of Plague without the Aid of Infected Rats." While agreeing in the main with our conclusions, which were based upon the circumstances of the late disastrous epidemic of pneumonic plague which swept across Manchuria during the winter months of 1910–11, Dr. Choksy contends that attacks of secondary pneumonia arising in bubonic cases, though theoretically potential sources of infection to those in contact with them, do not, as a matter of experience, cause infection of these persons; and that if any of those in contact with such cases do contract plague it must occur through the agency of rat fleas. In a brochure on "The Various Types of Plague and their Clinical Manifestations" which Dr. Choksy has forwarded to us, he has set out clearly the dangers arising from primary pneumonic plague. This type, he says, is the most insidious and virulent form of the disease, and at the same time highly infectious; it is usually contracted by the inhalation of the fine spray of the patient's sputum which teems with B. pestis. He also points out in his pamphlet that an apparent primary pneumonia "may not really be so, but a secondary development of malignant infection, with deep-seated buboes not felt during life-time, and early septicæmia." These instances, though pneumonic, have not in Dr. Choksy's experience proved infectious to those around the patients. It has, however, to be remembered that cases treated in well-constructed and well-administered hospitals such as those under Dr. Choksy's charge in Bombay are on a different footing from those occurring in dirty and ill-ventilated hovels. In the Manchurian epidemic, which spread so rapidly, it is surmised that some of the earlier cases of plague among the tarabagan trappers were treated in overcrowded and unventilated huts or tents, where the virulence of the infection might have become exalted, and the natural resistance of the occupants greatly reduced. It is worth mentioning in this connexion that the form of plague which frequently appears among the Mongols and other tribes in Central Asia, as well as among nomadic folk generally, is said to be nearly always of the pneumonic type, and that it is excessively fatal. This has been attributed to the extremely insanitary conditions under which these people mostly live. Their homes, as well as their persons, are described as being habitually dirty. They do not wash even their faces for many months on a stretch, and they wear their dirt-sodden clothing day and night, year after year, until the garments literally rot upon their backs. The occurrence of a secondary pneumonia in a case of plague treated under similar conditions would, in our opinion, be likely to lead to infection of persons in close proximity to the sufferer; and if a combination of circumstances arose, such as those which were met with in Manchuria in 1910–11, affording a sufficient supply of susceptible human material, a virulent and swiftly spreading epidemic might be originated. The Advisory Committee for the Investigation of Plague in India appear to regard secondary pneumonia as a possible source of danger, for one of the members of that body not long ago in a public address on plague made the following statement: "The universal experience in India has been that bubonic plague, whether it has become septicæmic or not, is for practical purposes not infective, unless it develops a secondary pneumonia."

THE FINGER PHENOMENON: A NEW SIGN OF ORGANIC HEMIPLEGIA.

SINCE Babinski discovered his invaluable sign of organic disease of the pyramidal tract several observers have described other reflex manifestations in the lower limb, but the upper limb has received comparatively little attention, and no sign comparable to the toe phenomenon has been described. In the majority of cases there is no difficulty in recognising an isolated monoplegia of cerebral origin or a paralysis of the arm accompanying hemiplegia, yet at times cases are seen in which the diagnosis between functional and organic paralysis of the upper limb is difficult. Again, in a small group of cases of hemiplegia dating from infancy the paralysed limbs or one of them (the upper) may be free from spasticity, and old anterior poliomyelitis may be suggested. If the lower limb has greatly improved or been only slightly involved the difficulty of diagnosis may be great. In the *Journal of the American Medical Association* of Nov. 11th, 1911, Dr. Alfred Gordon has described a new sign of organic hemiplegia, which he terms "the finger phenomenon" and which may be useful under these circumstances. The forearm of the affected limb is elevated and the elbow placed on a table. The wrist is then lightly grasped by the examiner's hand with the thumb against the pisiform bone and the other fingers on the dorsum of the wrist. Pressure is made with the thumb against the pisiform bone, especially on its radial side, care being taken not to produce pressure on the dorsum of the wrist where the extensor muscles are located. In organic hemiplegia the fingers of the patient's hand are seen to extend and sometimes to spread out in a

fan-like form. In some cases extension is observed only in the fourth and fifth fingers; in others all five extend, and in still others the thumb and the next two fingers. In old hemiplegia in which contracture is pronounced the phenomenon is not very marked, and may not be obtained. In recent hemiplegia (under six months) the reflex was usually prompt, but in some cases was elicited only after making two or three tests. As controls normal persons and patients suffering from brachial palsy of poliomyelitic and hysterical origin were examined.

THE NEW FATS.

IT is not so very long ago that the fatty substances essential in the human dietary were derived almost exclusively from an animal source. Beef, mutton, pork, milk, butter, or cream practically supplied the fatty needs of the body. The only vegetable fat hitherto consumed in important quantities was olive oil. It use, however, was generally limited to the salad, and not a few people prefer the salad without the addition of oil. Cod-liver oil, the most familiar example of a fish oil, was used medicinally because it was regarded to be readily assimilated, and so was held to be a certain and rapid source of energy. The important question of the digestibility of fats appears to have received attention chiefly in regard to animal fats. In physiological literature, at all events, it is difficult to find any definite conclusions as to the digestibility of vegetable fats, and yet the matter is of increasing importance, seeing how rapidly vegetable fats are being introduced into our daily articles of diet. The introduction of butter substitutes in the "seventies" created an opening for vegetable fats, and the industry in these fats is growing enormously at the present time. Margarine at first consisted of beef fat churned with milk and coloured, but now a very wide range of vegetable fats is available for making part, at any rate, of this butter substitute. There is a very large trade in sesame oil, cocoa-nut oil, palm-kernel oil, arachis oil, cotton-seed oil, sunflower oil, maize oil, poppy oil, and a number of other vegetable oils, all of which are destined for human consumption, chiefly in the form of butter substitutes. We are constantly told that these are wholesome, but occasionally it has happened that in the race for cheap sources a poisonous oil has been found and actually used in making a butter substitute, while several nut oils are known to have marked purgative properties. The time has arrived, we think, when the broad question of the suitability of vegetable fats, such as those just mentioned, for purposes of human consumption, compared with animal fats, should be thoroughly investigated and discussed. It is generally admitted that butter is the most digestible edible fat we possess, and if that is the case something should be done to ascertain whether the use of one or any of the vegetable fats as substitutes, on the enormous scale of the present day, is justified on sound physiological premises.

DIAGNOSIS OF ENTERIC FEVER BY CONJUNCTIVAL INSTILLATION.

AT first sight it would seem superfluous to search for a diagnostic test of typhoid fever; the Widal reaction is easily made, and the margin of error is small. It fails, however, in one respect, and that an important one in the case of typhoid fever; it is not likely to be positive until the disease is well on in its course. To meet this objection Chantemesse in 1907 applied the principle of Calmette's ophthalmo-reaction for the diagnosis of tuberculosis to typhoid fever and found it reliable. In the hands of other investigators, however, the test proved not quite so certain as its author's reports had suggested. A possible explanation of this variability is supplied by Dr. Charles R. Austrian, who reports his experiences of the test in the *Johns Hopkins Hospital Bulletin* for January, 1912. His earlier applications of this method of diagnosis led him to think that the negative results which he encountered in cases of undoubted typhoid fever might be due to variations in the strain of the infecting bacilli. To meet this objection he prepared the emulsion, to be used for instillation into the conjunctival sac, from 80 different strains of typhoid bacilli. The results obtained were encouraging; a positive reaction developed in 71 out of 75 patients with typhoid fever, while in 190 control cases (patients suffering from other diseases than typhoid fever) a reaction was seen only twice, in both instances this occurring in patients who had had typhoid fever previously. To carry out the test fresh preparations should be used; the patient should turn the head to the left if the right eye is selected; the lower lid should be partially everted, and one drop instilled into the lower conjunctival sac so that it runs towards the inner canthus. Immediate closure of the lids must be prevented, and the eye must not be rubbed. A positive reaction consists in congestion of the vessels of the caruncle and of the inferior palpebral conjunctiva, which reaches its maximum in six to ten hours (the membrane becoming deep purple), and persists for at least 20 hours, with lacrymation, purulent exudation, and bulbar suffusion. Atypical reactions may develop in non-typhoid cases, but these are more diffuse and less enduring. According to Dr. Austrian there is no difficulty in distinguishing between the two types. He believes that this reaction is similar to that devised by Calmette for the diagnosis of tuberculosis, in that it is the outcome of sensitisation of the patient's tissues to the toxins of the specific organism, and he makes the interesting suggestion that atypical responses occurring in non-typhoid persons are due to "group-sensitisation"—i.e., to sensitisation of the tissues to typhoid toxin by the action of the toxins of allied bacteria, such as B. coli communis. Perhaps the most important claim made for this method of diagnosis is the early stage of the disease at which a positive reaction is to be anticipated; in 18 out of 19 cases examined during the first week a positive result was obtained, and in 77 per cent. of the cases which reacted to the ophthalmic test the Widal reaction, applied at the same time, was negative. It should be added that there were no untoward or uncomfortable consequences.

INSANITARY BERTHS IN THE MERCHANT SERVICE.

THE Imperial Merchant Service Guild, consisting of captains and officers, is doing a good and a very necessary work by bringing pressure to bear upon the Board of Trade so as to secure better sanitation on board merchant ships. The agitation to which the late Mr. Plimsoll, "the sailor's friend," devoted his life was heartily supported by the general public, and something was done to prevent seamen sailing in "coffin ships." But a ship may be a coffin ship without sinking to the bottom of the sea. Bad sanitation may produce fatal results just as easily as a shipwreck. Thus, for instance, we have before us a letter addressed by an officer to the company he was serving and explaining why he is compelled to resign. His story runs as follows. When, as was frequently the case, the vessel shipped a sea the water would come through under the door into his private cabin, having first scoured out the adjoining lavatories and closets. These closets were divided off from the officers' quarters by a wooden partition which was neither water-tight nor air-tight, so that it did not prevent the unpleasant odours from penetrating the officers' berths, and they were frequented by 14 men. The Imperial Merchant

Service Guild urges that officers are entitled to separate cabins with sufficient room and adequate equipment, and the cabins should be situated in a part of the ship where proper rest and relaxation can be enjoyed. Officers' cabins at present are often very small, and two or three officers are made to share this insufficient accommodation. Then they are not only overcrowded, but at times are absolutely insanitary, as in the case mentioned above. If such conditions exist in regard to the officers, what must the quarters inhabited by the seamen and firemen be like? Some evidence as to the prevalence of pulmonary tuberculosis in the Merchant Service was given in a paper by Dr. Murdoch MacKinnon in THE LANCET last autumn.[1] This paper showed how great are the permanent disablement and loss of life from a preventable disease. From time to time also we have described the very unsatisfactory state of affairs that prevails at sea,[2] and lamented that it has been left to France, Austria, and other nations to enact laws that secured for their seafaring population much better sanitary conditions than prevail in the British Merchant navy. This is a question on which officers and men might well unite, and they should claim conditions at least equal to those which continental governments enforce in their merchant navies.

PELLAGRA IN NYASALAND.

PELLAGRA is a disease which, if practically unknown except by name to the profession at home, has within recent years more or less suddenly become of pressing importance from the epidemiological and other points of view. It is true that only two cases, apparently, have been reported in this country, but in America during the last few years there has been a prolonged and severe epidemic, which has ravaged more particularly the Southern States, neither white nor black being exempt, and in which many hundreds, if not thousands, of cases have occurred. Perhaps the term epidemic is rather inaccurate in this connexion, for the question which has agitated the profession in America, and which was one of the subjects of discussion at the Pellagra Conference in N. Carolina, is, how far can the appearance of the disease be said to be due to fresh introduction or extension, and how far simply to increased facility in recognising the affection? In the case of the recent disastrous American outbreak probably both factors are implicated. Pellagra is endemic in the Southern states of Europe, in Italy, Roumania, Bulgaria, and so on. It occurs in the same way in Lower Egypt, Algiers and the Red Sea Littoral. At a recent meeting of the Society of Tropical Medicine and Hygiene Dr. Hugh S. Stannus, one of the medical officers of the British Central Africa Protectorate, read an important paper on the occurrence of pellagra in Nyasaland, where hitherto the disease has not been known or at least not been recognised. Dr. Stannus, while acting as medical officer to the central native prison at Zomba, was struck by the appearance in certain inmates of a rhagades-like soreness at the corners of the mouth, associated with changes on the surface of the tongue, with the subsequent development of symmetrical skin eruptions on face and neck and elsewhere, and also with the development, at a later stage, of paretic symptoms. It was not until the whole cycle of symptoms had established itself that Dr. Stannus was convinced he was dealing with an outbreak of pellagra. There can be no doubt, from the description which he supplies, that the disease occurs in Nyasaland in typical and easily recognisable form. Apparently there is a seasonal maximum in April and October. The earliest symptoms are this rhagades-like condition at the muco-cutaneous borders of the angles of the mouth, a similar condition at the free margin of the prepuce, and a curious glossitis which denudes he tongue of epithelium and renders it shining and bright pink in colour. Then appears the characteristic skin eruption, as a rule on the extensor surfaces of the forearms, in the triangles of the neck, on cheeks, nose, and forehead, on the back of the hands, on the shins, and the dorsum of the feet. The eruption preserves a remarkable bilateral symmetry. Gastro-intestinal and other general symptoms often occur in the early stages. Of great interest and pathogenic significance are the phenomena indicative of invasion of the nervous system. Headache, mental apathy, and moroseness are specially noted by Dr. Stannus. There is commonly a sadness of facial expression and an inability or unwillingness to smile which are almost pathognomonic. Cranial nerve symptoms, in the shape of transient amblyopia, central scotomata, loss of sphincter tone in the iris, and deafness may occur. Paresis or paralysis of the lower extremities is common, tremor of the limbs is the same, subjective sensory phenomena are also very frequent, consisting of tingling and burning pains in the feet, toes, and calves, often associated with tenderness of the latter on pressure. The organic sphincters are not impaired in function. There can be little doubt that pellagra is a toxæmia affecting more particularly the central and peripheral nervous system, rendering the skin more liable to irritation by the sun's rays, and recurring in successive years in a chronic form, but its pathology, epidemiology, and etiology are still to be elucidated. Dr. Stannus suggests that the nervous lesions are produced by a toxin entering the spinal theca by the lymphatic spaces of the posterior roots, setting up a posterior lepto-meningitis and then invading the cord. The disease presents suggestive resemblances, especially in symptoms, to certain well-known nervous diseases, on the etiology of which, therefore, it may some day prove by analogy to shed light. In view of certain current opinions as to the causation of the disease, it is noteworthy that Dr. Stannus's cases only rarely had maize as an article of food; their staple diet consisted of rice. There is reason to suppose that pellagra may be associated with the occurrence of flies of the simuliidæ family, whose habitat is in the neighbourhood of running streams. It is to be hoped that Dr. Stannus's suggestive paper will be provocative of further investigation into the subject of pellagra, as the disease is one, as above remarked, of singular interest, whose recent expansion is a fact of serious import.

ADUMBRATIONS OF ANTISEPSIS.

ABOUT a century before the great discoveries of Pasteur and Lister it is curious to find William Alexander, an Edinburgh surgeon, discussing the animalcular origin of putrefaction and putrid, or, as we should now say, septic, diseases, and dismissing as untenable what he supposes to be a theory founded on inaccurately conducted experiments. The believers in the rejected theory included such names as those of Plenciz, Linnaeus, Buffon, Needham, Robert Boyle, and Athanasius Kircher, a Jesuit of universal learning, who, in 1658, published "Scrutinium Physico-medicum Pestis, Origo, Causæ, Prognostica," &c., a work in which the plague is attributed to what for lack of a better phrase we must call "a bacterial origin." But though in 1771 Alexander will have nothing to do with what has since triumphantly developed into the germ theory of disease, he nevertheless speculates and acts almost as though the theory were already an accepted dogma. Thus in one of his "Experimental Essays," published in 1768, three years

[1] THE LANCET, Sept. 23rd, 1911, p. 885.
[2] THE LANCET, Feb. 8th, 1908, p. 457, March 27th, 1909, p. 945, and Sept. 17th, 1910, p. 880.

earlier than his work inquiring into the origin of putrid diseases, under the title "Essay on the External Application of Antiseptics," he resembles a child playing at hide-and-seek and growing decidedly "warm." His approximation to certain truths, which, as a rule, it is supposed, are entirely modern, appears in such a passage as the following: "Sir John Pringle, as far as I know, was the first who attempted to sweeten putrid flesh by immersing it in antiseptics. Dr. Macbride [another Edinburgh surgeon who published just prior to Alexander] has improved his hints ..... by suspending it in the steams which arose from them. It has been an established fact these many years that poultices of bark or spirituous antiseptic fomentations, applied to gangrened parts, have very much contributed to recover them." We are here within an ace of the treatment of wounds by antisepsis. In the succeeding passage we find ventilation insisted on in an age supposed to be peculiarly careless in the conduct of the sick-room. "At present almost every practitioner who attends the sick in putrid diseases orders the room to be ventilated, washed with vinegar, or fumigated with aromatics; and what are all these but so many methods of applying antiseptics externally? I am persuaded that if we had reasoned fairly upon them they would have served as so many leading hints to have discovered that a human body may be sweetened and recovered from putrefaction by being bathed in antiseptics as well as a part of any other animal." Though rejecting the animalcular theory Alexander plainly recognises that putrid diseases are caused by what he calls "putrid particles," and he argues that evacuants are useless as a means of treatment. "Were we to proceed entirely by the evacuatory method, so long as we left one particle it would still be an infected one."

LIFE INSURANCE IN INDIA.

WE have received a copy of a paper read before the Life Assurance Medical Officers' Association on behalf of Dr. Adrian Caddy, surgeon to the Hindu Marwari Hospital, Calcutta, on life insurance in India. Some interesting points are brought forward which indicate the differences between those individuals presenting themselves for examination for life insurance in this country and those who are examined in India. In regard to the native lives Dr. Caddy finds that the native is usually a shorter man than the European, that height for height the native weighs the same on an average as the European, and that there is no evidence to show that his tissues are any lighter than those of a European. The native is very subject to glycosuria, due probably to his carbohydrate diet; he is also liable to develop hydrocele, but the reason for this is not evident. Dr. Caddy is of opinion that opium and hemp drugs are not commonly consumed by the insuring classes. With regard to Europeans, Dr. Caddy offers some interesting suggestions, but he points out that they are the results of his own inquiries, and must only be taken as such. He maintains that Europeans do not acclimatise in the tropics, and submits as a proof of this statement the inability to withstand the tropical sun without any head covering, and after years of residence in hot climates there seems to be a greater liability to sunstroke than on arrival. He further contends that the children of Europeans who have been sent "home" when 4 or 5 years old for their education are generally not so fine physically as their parents, owing to the debilitating influence on their constitutions of the tropical climate at an important growing period of their lives. He also thinks that it is a mistake for parents who have lived in India to send their children when grown up to that country to earn their livelihood; this, however, is very commonly done, but Dr. Caddy believes that it leads to physical degeneration. All these are points which would have an important bearing in arriving at conclusions as regards the rating to be advised on candidates presenting themselves for examination for life assurance. But little, we believe, has been written on life assurance in India, and therefore Dr. Caddy's remarks are particularly worthy of attention.

FOUR lectures on Sleeping Sickness will be delivered at the City of London School, Victoria Embankment, by Dr. F. M. Sandwith, Gresham professor of physic, on Tuesday, Wednesday, Thursday, and Friday, Feb. 13th–16th, at 6 P.M. The lectures are free to the public.

THE ORIGIN AND WHOLESOMENESS OF THE SALINE WATERS IN THE LONDON BASIN.

BY JOHN C. THRESH, M.D. VICT., D.SC. LOND.,
MEDICAL OFFICER OF HEALTH, ESSEX COUNTY COUNCIL; LECTURER ON PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE.

THE waters derived from the chalk and Thanet sands under south-eastern Essex, London, and other places are characterised by their great softness and by the presence of considerable quantities of sodium chloride, sodium sulphate, and sodium carbonate. The proportions of these salts vary considerably, and in some cases, as, for example, near the coast from Harwich down to Foulness Island, and near the Thames at Barking, the Isle of Dogs, &c., the water shows undoubtedly the effect of tidal water infiltration. For years past I have been engaged in investigating the origin of the saline constituents of these potable waters and in plotting the various sources on the map and tracing the chalk water from the north-west of Essex and the very saline and brackish water from the north-east. I surmised that these waters mingled in their course south towards London, and that in some way, whilst travelling, the lime salts disappeared and were replaced by soda salts. This is not the place to record my experiments, but the results are simple and conclusive. The alkaline saline London Basin water is a mixture of chalk water with a small quantity of sea water, which by filtration through the Thanet sand undergoes a marvellous change. This change can be effected in the laboratory, but to completely remove all the lime salts in a short time it is first necessary to treat the sand either with dilute acid or with brine. After either treatment mere filtration of a mixture of sea water and chalk water converts it into a water typical of that in the London Basin. One such result may be recorded as an example, and the mixture contained, purposely, an excessive quantity of sea water. As a typical chalk water, that from the water-works at Halstead on the north border of the chalk outcrop was selected, and this was mixed with 3 per cent. of sea water from Clacton-on-Sea. A portion was analysed and the remainder simply filtered through six inches of Thanet sand which had been washed with brine and then with distilled water. The filtrate was collected and examined.

Analysis of Mixed Chalk Water and Sea Water.
(*In parts per 100,000.*)

	Before filtration through Thanet sand.	After filtration.
Total hardness	50·0 deg.	0·5 deg.
Free ammonia	0·002	0·105
Organic ammonia	0·004	0·009
Calcium carbonate	25·25	1·0
Magnesium carbonate ...	2·45	0·0
Magnesium sulphate	12·30	0·0
Magnesium chloride	6·65	0·0
Sodium carbonate	9·0	31·85
Sodium sulphate...	0·0	16·30
Sodium chloride...	113·1	126·2
Silica, &c.	1·35	2·65
Total solids...	161·10	178·0

Using smaller quantities of sea water, it is possible to produce waters practically identical with the water from any deep well in the London Basin.

To make the proof conclusive it was argued that if these salts came from sea water they would be associated with bromides found in all tidal waters. This proved to be the case and led to an interesting investigation, not yet completed, on the detection of various compounds of iodine and bromine in sea water and other saline waters. Here it is sufficient to state that when proper precautions are taken bromides can be detected in all these waters, and iodides have been detected in those specially examined for that purpose. The quantity found, however, is exceedingly minute and most easily overlooked. Incidentally the source of the ammonia found in these deep well waters is also demonstrated. It is produced by the reduction of nitrates by the ferruginous sand.

Of the wholesomeness of such of these waters as are used for public supplies at Southend, Colchester, Witham, Chelmsford, and other places there appears to be no doubt, but near the coast in certain parts of Essex the only deep well water obtainable resembles that the analysis of which is given above, and which contains 70 grains and upwards of common salt per gallon. So far these waters have only been used for supplying farms or a few cottages, and when such a water has been obtained in boring to obtain a public supply it has been unhesitatingly condemned as being unsuitable for the purpose. Fifty grains of salt to a gallon of water imparts a saline taste perceptible to many people, and when the amount is increased to 70 grains everyone can detect it. The comparatively few people I have been able to interrogate acknowledge that at first they would not have used the water for drinking purposes if they could have obtained any other, but that they soon became accustomed to it and like it, and have never experienced any ill-effect which could be attributed to its use.

The subject has recently assumed greater importance since it is now proposed to utilise such a saline water as a supply for a population of several thousands. I have suggested mixing it with an equal volume of spring water or subsoil water, but unfortunately a sufficient quantity of a sufficiently good water does not appear to be available for the purpose. The water in question contains about 85 grains of salt per gallon, so that assuming each person drinks three pints per diem, each would imbibe 31 grains of salt. Many wild and random statements are made about the injurious effects of salt, but no proof seems to be adduced that its continued use in moderate quantities has produced illness of any kind. In Essex thousands of people are entirely dependent upon supplies containing 55 grains of salt per gallon, and these localities are about the healthiest in the county. Will the additional 30 grains per gallon be deleterious? Or, in other words, if water containing 21 grains of salt in the three pints drunk daily is perfectly wholesome, is it likely that a water containing 31 grains in the same quantity will be unwholesome? My opinion is that the water is quite wholesome and that after the inhabitants have become accustomed to its use no objection will be found in it.

Deep well waters derived from the Thanet sands or chalk beneath the greater part of London only contain 8 to 26 grains of salt per gallon, with a correspondingly smaller quantity of sodium carbonate and sulphate, and are very pure, palatable, soft, and well adapted for all domestic and most manufacturing purposes. Bacteriologically they are not invariably so pure as would be expected from such a deep source, but as it is practically impossible for dangerous pollution to occur the bacterial contents can usually be disregarded. A recent experience, however, shows that pollution is possible. When investigating the cause of the bacterial pollution of such a well I discovered that a similar well a few hundred yards away had been converted into a kind of cesspool, and that polluting matter had been poured into it for years. However, at the time of my investigation the well had been filled in and the polluting matter carried by a drain into the public sewer. The experience has, however, impressed upon me the necessity for making very careful investigations before asserting that pollution is impossible.

London Hospital Medical College, E.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Jan. 26th, Sir THOMAS BARLOW, Bart., K.C.V.O., President, being in the chair.

The PRESIDENT referred to the great loss the profession had sustained by the death of Sir Henry T. Butlin, formerly President of the Royal College of Surgeons of England, and it was resolved that a letter of sympathy should be sent from the College to Lady Butlin.

The following gentlemen having passed the required examination were admitted Members of the College:—Charles Hubert Bond, M.D. Edin., Alfred Joseph Clark, M.B. Camb., L.R.C.P., Georg Dorner, M.D. Königsberg, L.R.C.P., William Johnson, M.D. Lond., L.R.C.P., Indarjit Singh, M.B. Camb., I.M.S., and Charles Wilfred Vining, M.D. Lond.

Licences to practise were granted to 92 gentlemen who had passed the necessary examinations.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England to the following gentlemen: Arthur George Atkinson, Robert Vickers Clayton, Francis Gerard Hamilton Cooke, Maneckjee Merwanjee Cowasjee, Frank Elton Cox, George Henry Dupont, Josephine Letitia Denny Fairfield (under the Medical Act, 1876), William Miller Fairlie, William Robert Gibson, John Andrew Hagerty, George Crichton Jackson, Satyaranjan Maitra, Mammatha Nath Mitra, John George Owen, Henry Christian Ernest Quin, Jessie Annie Scott (under the Medical Act, 1876), Frederick Meadows Turner, and Arthur Christopher Watkin.

A Diploma in Tropical Medicine was granted jointly with the Royal College of Surgeons of England to James Bruce-Bays.

The following communications were received:—1. From the secretary of the Royal College of Surgeons of England, reporting proceedings of the Council of that College on Nov. 9th, Dec. 14th, and Jan. 11th last. 2. From Mr. C. S. Jackson, informing the College that the late Dr. Hughlings Jackson bequeathed a portrait of himself to the College. 3. From Mr. Frank Glover, offering to the College a gold pencil case, formerly the property of Sir Henry Halford, Bart., President of the College. 4. From Mr. Ernest M. Wilks, informing the College that the late Sir Samuel Wilks, Bart., bequeathed to the College a portrait of himself and a gold cup. The above gifts were accepted, and the thanks of the College ordered to be returned to the writers of the letters. 5. From the Doctors' Wives Defence Movement concerning certain effects of the Insurance Act. 6. From Dr. James Kerr Love, on behalf of the National Bureau for Promoting the Welfare of the Deaf, concerning the delivery of proposed lectures. The matter was referred to the Censors' Board.

The PRESIDENT announced that he had nominated Sir James F. Goodhart to be the Harveian orator for this year, and Dr. D. B. Lees to be the Bradshaw lecturer, and that the Council had appointed Captain R. McCarrison, I.M.S., to be the Milroy lecturer for 1913. The President also announced that he had nominated Dr. Frederick T. Roberts to be the representative of the College on the governing body of the University of Wales. Dr. W. Collier, Dr. F. W. Mott, Dr. H. P. Hawkins, and Dr. H. D. Rolleston were elected councillors.

Sir Francis Champneys was re-elected a representative of the College on the Central Midwives Board; Sir Dyce Duckworth was re-elected a representative on the governing body of the University of Liverpool; and Dr. Samuel West was appointed a representative of the College on the court of governors of the University of Birmingham.

Certain addenda were made to the scheme of the new examinations in psychological medicine, the chief of which was to the effect that the appointment of examiners should be made by the Censors' Board.

A report was received and adopted from the Committee of Management dated Dec. 5th, 1911. The committee recommended that the following institutions should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics: Royal Dental Hospital, London, and Mill Hill School. The committee also recommended that Rhodes University College,

Grahamstown, South Africa, should be added to the list of institutions recognised by the board for instruction in chemistry, physics, and biology.

It was resolved that a committee of the College should be formed to watch the interests of the Licentiates of the College under the provisions of the Insurance Act, with power to confer with any other body established for similar purposes should the committee see fit to do so.

A debate then followed upon the invitation of the National Insurance Commissioners to the College to send representatives to the conference to be held to-day (Friday, Feb. 2nd), in the course of which the President adjourned the Comitia until Tuesday, Jan. 30th.

The adjourned Comitia was held on Tuesday, Jan. 30th, Sir THOMAS BARLOW, K.C.V.O., the President, being in the chair.

A report was received from the Representative of the College on the General Medical Council, on the proceedings of the Council during its session in November last.

After some formal business had been transacted the College proceeded to discuss a letter which had been received from the National Health Insurance Commission. The letter was as follows:—

National Health Insurance Commission,
Whitehall, London, S.W.,
24th January, 1912.

SIR,—The National Health Insurance Commissioners have decided, for their assistance in bringing the Insurance Act into operation, to take the earliest opportunity of personally conferring with representatives, widely selected, of the chief sections of the community specially concerned. Conferences with representatives of prospective insured persons have already taken place, and it is considered that the time has now arrived when it would be of material assistance to the Commissioners to obtain, in a conference, suggestions from representatives of the medical profession on certain important questions of procedure preliminary to bringing the Act into operation.

The National Health Insurance Joint Committee and the Insurance Commissioners for England, Scotland, and Wales respectively propose accordingly to hold a Conference on Friday, Feb. 2nd, with representatives of the medical profession; and the Royal College of Physicians in London is invited to appoint two members to attend the Conference, which will be held at 3 P.M. A further communication will be addressed to you as to the place of meeting. A similar invitation is being addressed to the General Medical Council, the British Medical Association, and to other medical bodies.

The point which it is specially desired to discuss relates to the selection of the medical members of the Advisory Committee by whom the Commissioners must be advised in the framing of regulations in accordance with Section 58 of the Act[1]; and the Commissioners will also be glad to hear the views of those present on other matters of procedure in bringing the Act into operation which the representatives of the medical bodies may desire to bring forward.

I am, Sir, your obedient servant,
R. W. HARRIS,
Assistant Secretary of the Joint Committee.

The Secretary, Royal College of Physicians in London.

The following motion was proposed and seconded:—

That in view of the letter from the Insurance Commissioners the College should proceed to appoint Representatives to place before the Commissioners the resolutions of the College respecting the Insurance Bill, in so far as these resolutions may not have been incorporated in the Insurance Act.

To this an amendment was proposed and seconded as follows:—

That in view of the letter from the Insurance Commissioners the College should proceed to consider the invitation of the National Insurance Commissioners to confer with them on the methods of putting the Act into operation.

This was carried by a large majority, and thus became the substantive motion, and carried.

The following series of suggestions were then put and approved of:—

1. That the Insurance Act, as it stands, or even after any modification in it which the Act empowers the Insurance Commissioners to make, is not adapted to secure the benefits "of insurance against loss of health and the prevention and cure of sickness" which are its stated purpose to provide; and that the coöperation of the medical profession in carrying out the operations of the Act is not possible under the Act or under any modifications of it empowered to the Commissioners without inflicting grave injury on the profession.

Therefore:—

2. The College, while desirous of doing all in its power to promote the objects of the Act in reference to the health of the community, is not prepared to accept the invitation of the National Health Insurance Commissioners to the conference on Feb. 2nd for the purposes therein stated of "Selection of Medical Members of the Advisory Committee and" for other matters of procedure in bringing the Act into operation.

3. That the College would be happy to promote an amending Act by which the interests of the public health would be promoted and the interests of the medical practitioners and medical science be safeguarded.

The following motion was then proposed and seconded:—

That the President be requested, with the assistance of such Fellows as he may nominate, to draw up and send a reply to the invitation of the Joint Commissioners in accordance with, and giving the substance of, these resolutions.

To this an amendment was proposed and seconded as follows:—

That the College accept the invitation to discuss the election of medical members of the Advisory Committee, but is not at present in a position to discuss with the Commissioners any other matters of procedure in bringing the Act into operation.

This amendment was lost by a large majority, and the original motion being put was carried.

The PRESIDENT then dissolved the Comitia.

[1] Section 58 of the Act is as follows: "The Insurance Commissioners shall, as soon as may be after the passing of this Act appoint an Advisory Committee for the purpose of giving the Insurance Commissioners advice and assistance in connexion with the making and altering of regulations under this part of this Act, consisting of representatives of associations of employers and approved societies, of duly qualified medical practitioners who have personal experience of general practice, and of such other persons as the Commissioners may appoint, of whom two at least shall be women."

BRITISH MEDICAL BENEVOLENT FUND.

AT the January meeting of the committee 14 cases were considered and grants amounting to £86 made to 11 of the applicants. Appended is an abstract of the cases assisted:—

Daughter, aged 44, of late M.R.C.S. No income, and has been unable to earn a living for some years on account of increasing deafness. Finds she can hear with an instrument recommended by an aural surgeon and asks for assistance to purchase it. Voted £5.

M.B., C.M. Edin., aged 57. Has a small practice in Hampshire, but finds great difficulty in obtaining his fees and asks for a little help. Voted £5.

Widow, aged 41, of M.B., C.M. Edin. Quite unprovided for at husband's recent death after a long illness, and has four young children, the eldest only being 5 years old. Voted £10.

Daughter, aged 57, of late M.R.C.S. Is most willing and anxious to work, but has broken down in health and been obliged to give up a situation as companion. Relieved once, £12. Voted £12.

Daughter, aged 74, of late M.R.C.S. Supplements an income of a few shillings a week by needlework, but is unable to earn as much as formerly on account of rheumatism and failing eyesight. Relieved 13 times, £125. Voted £12.

Daughter, aged 59, of late M.R.C.S. Has supported herself for more than 30 years as governess, school matron, &c., but is now unable to obtain a suitable post. Relieved five times, £60. Voted £12.

Widow, aged 56, of M.R.C.S. No income; no children; and unable to maintain herself on account of ill-health. Relieved eight times, £80. Voted £2, and case to be reconsidered.

Widow, aged 60, of L.R.C.P., L.R.C.S.Irel. No income, and is practically incapacitated by the loss of her right hand. Children unable to help. Relieved eight times, £68. Voted £12.

M.D. Aberd., aged 59. Used to have a fair practice in a Midland town, but has been incapacitated for several years by spastic paralysis, and is entirely dependent on pensions obtained from charitable societies. Three children, the eldest only 13 years old. Relieved three times, £33. Voted £5.

Widow, aged 66, of M.D. Edin. Supplements a small weekly allowance from relations by taking a boarder, and asks for a little help to meet unavoidable expenses. Relieved twice, £12. Voted £6.

Daughter, aged 50, of late F.R.C.S. Has supported herself as a companion, but at present has no post and is not in very good health. Relieved six times, £35. Voted £5.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8745 births and 5559 deaths were registered during the week ending Jan. 27th. The annual rate of mortality in these towns, which had been 15·3, 15·4, and 14 8 per 1000 in the three preceding weeks, rose to 16 5 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual rate of mortality in these large towns averaged 15·5 per 1000, while in London during the same period the average annual death-rate did not exceed 15·0 per 1000. The annual death-rates in the several towns last week ranged from 6 2 in Edmonton, 7·8 in Eastbourne, 8·5 in Hornsey, 9·6 in Grimsby, and 10·1 in Southend-on-Sea, to 23·1 in Newport (Mon.), 24·3 in West Bromwich, 25·3 in Merthyr Tydfil, 29·8 in Walsall, and 31·5 in Dudley.

The 5559 deaths from all causes in the 94 towns were 580 in excess of the number in the previous week, and included

311 which were referred to the principal epidemic diseases, against 323 and 297 in the two preceding weeks. These 311 deaths from the principal epidemic diseases included 94 from whooping-cough, 72 from measles, 53 from diphtheria, 47 from infantile diarrhœal diseases, 26 from scarlet fever, and 19 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week did not exceed 0·9 per 1000, and was equal to the average rate in the three preceding weeks. The deaths attributed to whooping-cough, which had been 78, 88, and 81 in the three preceding weeks, rose to 94 last week, and caused the highest annual death-rates of 1·3 in Gateshead, 1·4 in Coventry, 1·5 in Tottenham and in West Bromwich, 1·7 in Walsall, 1·8 in Swansea, and 2·5 in Merthyr Tydfil. The deaths referred to measles, which had declined from 83 to 64 in the three preceding weeks, rose to 72 last week; the highest death-rates from this disease were 1·3 in Wallasey and in Swansea, 1·8 in Oldham, and 2·1 in Warrington. The fatal cases of diphtheria, which had been 49, 69, and 60 in the three preceding weeks, declined to 53 last week, and included 18 in London and its 14 suburban districts, 5 in Leeds, and 3 in Liverpool. The deaths attributed to infantile diarrhœal diseases, which had averaged 57 in the three preceding weeks, declined to 47 last week, of which 17 were registered in London, 4 in Birmingham, and 3 in Newcastle-on-Tyne. The deaths referred to scarlet fever, which had been 19 in each of the two previous weeks, rose last week to 26, and included 4 in Leeds, 3 in London, and 2 each in Birmingham, Liverpool, and Middlesbrough. The fatal cases of enteric fever, which had been 24, 20, and 17 in the three preceding weeks, were 19 last week; 4 deaths were registered in Sheffield, 3 in London, 2 in Stoke-on-Trent, and 2 in Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily decreased from 2213 to 1654 in the ten preceding weeks, had further declined to 1562 on Saturday last; 158 new cases of this disease were admitted to these institutions during the week, against 193, 165, and 162 in the three preceding weeks. These hospitals also contained on Saturday last 1209 cases of diphtheria, 328 of whooping-cough, 116 of measles, and 50 of enteric fever, but not one of small-pox. The 1376 deaths from all causes recorded in London were 159 in excess of the number in the previous week, and were equal to an annual death-rate of 15·9 per 1000. The deaths referred to diseases of the respiratory system, which had been 290 and 303 in the two preceding weeks, further rose to 333 in the week under notice, but were 41 below the number registered in the corresponding week of last year.

Of the 5559 deaths in the 94 large towns last week, 190 were referred to different forms of violence, and 470 were the subject of coroners' inquests. The causes of 61, or 1·1 per cent., of the deaths registered in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Nottingham, Portsmouth, and in 63 other smaller towns. The 61 uncertified causes of death last week included 10 in Birmingham, 10 in Liverpool, 5 in Stoke-on-Trent, and 4 each in London, in Dudley, and in Manchester.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns having an estimated population of 2,182,400 persons in the middle of this year, 1108 births and 740 deaths were registered during the week ending Jan. 27th. The annual rate of mortality in these towns, which had been 18·7 and 17·7 per 1000 in the two preceding weeks, rose to 17·3 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual rate of mortality in these Scotch towns averaged 17·7 per 1000, and was 2·2 per 1000 above that recorded in the 94 large English towns during the same period. The annual death-rates in the several Scotch towns last week ranged from 7·6 in Falkirk, 9·9 in Partick, and 10·0 in Motherwell, to 20·4 in Glasgow, 28·2 in Greenock, and 31·1 in Ayr.

The 740 deaths from all causes in the 18 Scotch towns were 15 in excess of the number in the previous week, and included 89 which were referred to the principal epidemic diseases, against 82 and 103 in the two preceding weeks. Of these 89 deaths, 39 resulted from measles, 18 from whooping-cough, 13 from diphtheria, 11 from infantile diarrhœal diseases, 4 from scarlet fever, and 4 from enteric fever, but not one from small-pox. These 89 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·1 per 1000, or 1·2 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had increased from 34 to 56 in the three preceding weeks, declined to 39 last week, of which 22 were recorded in Glasgow, 6 in Edinburgh, and 3 in Aberdeen. The 18 deaths referred to whooping-cough were equal to the number in the previous week, and included 8 in Glasgow, 3 in Ayr, and 2 in Aberdeen. The fatal cases of diphtheria, which had been 10 in each of the two preceding weeks, rose to 13 last week; 6 deaths occurred in Glasgow, 2 in Edinburgh, and 2 in Ayr. The 11 deaths attributed to infantile diarrhœal diseases were two in excess of the average in the three preceding weeks, and included 5 in Glasgow, 2 in Dundee, and 2 in Hamilton. The deaths referred to scarlet fever, which had been 11, 6, and 6 in the three preceding weeks, further declined to 4 last week, 2 of which were registered in Aberdeen. Of the 4 fatal cases of enteric fever, which were equal to the number in the preceding week, 3 were recorded in Glasgow and 1 in Greenock.

The deaths referred to diseases of the respiratory system, which had been 147 and 120 in the two preceding weeks, rose to 133 last week; and 24 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 602 births and 495 deaths were registered during the week ending Jan. 27th. The annual rate of mortality in these towns, which had increased from 18·0 to 21·8 per 1000 in the four preceding weeks, further rose to 22·3 per 1000 in the week under review. During the first four weeks of the current quarter the mean annual death-rate in the 22 Irish towns averaged 20·8 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 15·5, while in the 18 Scotch towns it was equal to 17·7 per 1000. The annual death-rates last week in the several Irish towns were equal to 23·5 in Dublin (against 15·9 in London), 27·5 in Belfast, 26·5 in Cork, 15·3 in Londonderry, 16·3 in Limerick, and 13·3 in Waterford; while in the 16 smallest of these Irish towns the death-rate last week did not exceed 10·7 per 1000.

The 495 deaths from all causes in the 22 Irish towns were 12 in excess of the number in the previous week, and included 30 which were referred to the principal epidemic diseases, against 28 and 41 in the two preceding weeks; of these 30 deaths, 15 resulted from whooping-cough, 5 from diarrhœal diseases, 3 from measles, 3 from scarlet fever, 3 from diphtheria, and 1 from enteric fever, but not one from small-pox. These 30 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·4 per 1000; the death-rate from these diseases did not exceed 0·9 in the 94 English towns, while in the 18 Scotch towns it was equal to 2·1 per 1000. The deaths attributed to whooping-cough, which had increased from 4 to 19 in the three preceding weeks, fell to 15 last week, and comprised 12 in Belfast and 3 in Dublin. The deaths referred to diarrhœal diseases, which had been 4 and 11 in the two preceding weeks, declined last week to 5, all of which related to infants under two years of age. The 3 fatal cases of diphtheria were equal to the average in the two preceding weeks. The 3 deaths attributed to scarlet fever were equal to the average in the three preceding weeks, and included 2 in Dublin and 1 in Belfast. The 3 fatal cases of measles were registered in Dublin, and that of enteric fever in Belfast.

The deaths referred to diseases of the respiratory system, which had steadily increased from 83 to 111 in the five preceding weeks, further rose to 152 last week. Of the 495 deaths from all causes in the 22 Irish towns, 126, or 25 per cent., were recorded in public institutions, and 9 were attributed to different forms of violence. The causes of 15, or 3·0 per cent., of the total deaths in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 English towns the proportion of uncertified causes of death last week did not exceed 1·1 per cent.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Frederick S. Heuston, C.M.G., is placed on retired pay (dated Jan. 22nd, 1912).

The undermentioned Majors to be Lieutenant-Colonels:—Stephen F. Clark, vice T. W. O'H. Hamilton, C.M.G., retired (dated Nov. 4th, 1911); Edward M. Hassard, vice W. W. Pike, D.S.O., promoted (dated Nov. 9th, 1911); Brevet Lieutenant-Colonel Sir William B. Leishman, F.R.S., vice J. M. Irwin, promoted (dated Dec. 11th, 1911); James Thomson, vice Sir W. B. Leishman, F.R.S., supernumerary (dated Dec. 11th, 1911); Gerald T. Rawnsley, vice F. S. Heuston, C.M.G., retired (dated Jan. 22nd, 1912); and Brevet Lieutenant-Colonel Alfred P. Blenkinsop, vice G. T. Rawnsley, supernumerary (dated Jan. 22nd, 1912).

Captain Carlisle Kelly is placed temporarily on the half-pay list on account of ill-health (dated Jan. 5th, 1912).

Lieutenant Thomas A. Weston, from the seconded list, is restored to the establishment (dated Dec. 1st, 1911).

Colonel W. G. A. Bedford, C.M.G., principal medical officer, South China, has taken up duty as Principal Medical Officer of the London District, rendered vacant by the retirement of Colonel A. Peterkin. Brevet-Colonel R. H. Firth, sanitary officer, Army Headquarters, Simla, has been appointed an Honorary Surgeon to His Excellency the Viceroy. Lieutenant-Colonel R. L. R. Macleod has been posted to Devonport in charge of the Military Hospital and appointed Senior Medical Officer of the South-Western Coast Defences. Lieutenant-Colonel J. J. C. Donnett has taken up duty in the Straits Settlements as Senior Medical Officer. Lieutenant-Colonel J. M. F. Shine has been appointed Senior Medical Officer at Jersey, in succession to Lieutenant-Colonel F. P. Nichols, who has been appointed as Medical Officer in Charge at Bodmin. Lieutenant-Colonel C. T. Blackwell has been appointed to command the Station Hospital at Rangoon. Lieutenant-Colonel C. A. Lane has been placed under orders to embark for a tour of service in India.

Major T. E. Fielding has taken up duty in the London District. Major H. S. Roche, adjutant of the Royal Army Medical School of Instruction at Leeds, has been posted for duty at Lincoln. Major H. W. Grattan has been posted to Benares. Major A. Chopping has been posted to the Eastern Command on return from India. Major H. H. Norman has been appointed for duty at Kasauli. Major A. C. Fox, on return from North China, has been posted to the Dublin District. Major A. G. Thompson has been selected for appointment to command the Station Hospital at Pachmarhi, with effect from March 1st next. Major J. McD. McCarthy has taken up duty as Specialist Sanitary Officer to the Second (Rawal Pindi) Division. Major J. G. McNaught has been appointed to the Aldershot Command Major G. H. Goddard has taken over charge of the Helena Hospital for Women and Children at Shorncliffe, in succession to Major S. H. Fairrie. Major L. P. More has been posted for duty with the Ninth (Secunderabad) Division.

Captain T. S. Blackwell has been appointed to the Medical Charge of the 1st Battalion, Royal Irish Rifles, during the movement of this regiment from Maymyo, Burma, to Kamptee. Captain V. T. Carruthers has joined the Cork District. Captain W. Egan has been granted eight months' general leave of absence home from India, at the termination of which he will revert for duty on the home establishment. Captain R. L. Argles has been appointed to the Medical Charge of the 23rd Fortress Company of the 3rd Sappers and Miners, stationed at Aden, in succession to Captain A. D. O'Carroll. Captain W. C. Smales, in charge of the Cantonment General Hospital at Poona, has been granted eight months' leave of absence home from India. Captain A. D. Jameson, from Aldershot, has taken up duty as Specialist in Dermatology and Venereal Diseases at the Station Hospital, Meerut. Captain J. Mackenzie has been transferred from Pirbright to the London District. Captain F. W. W. Dawson has left Dublin for a tour of duty in India. Captain H. C. Winckworth has been transferred from the Aldershot Command to the Woolwich District for duty at the Royal Herbert Hospital. Captain J. H. Graham, on return from Gibraltar, has been posted to Kilworth Camp. Captain F. A. McCammon has joined the Station Hospital at Poona for duty. Captain G. E. Ferguson has been appointed to Winchester. Captain J. L. Jones has been posted to the Eighth (Lucknow) Division for duty with the Southern Army. Captain H. Rogers has been detailed for a tour of service at Malta. Captain A. H. Heslop has been appointed for duty on board the transport s.s. *Rohilla*, which left Karachi for Southampton on Jan. 31st.

Lieutenant J. A. Manifold has been placed under orders for a tour of service in Bermuda. Lieutenant A. S. M. Winder, from the Curragh, has joined the Station Hospital at Lucknow. Lieutenant J. Gilmour, Devonport, has been appointed to the Military Hospital at Cosham.

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of the following officers of the Indian Medical Service:—Captains to be Majors (dated July 27th, 1911): Francis Victor Owen Beit and Matthew Corry. Lieutenants to be Captains (dated August 1st, 1911): Reginald Broughton Lloyd, Hugh Stott, and Gerald Lewis Colhoun Little.

The King has also approved of the retirement of Lieutenant-Colonel Charles Henry Bedford (dated Dec. 18th, 1911).

Lieutenant-Colonel T. W. Irvine has been selected to officiate as Agency Surgeon, First Class and Chief Medical Officer in the North-Western Frontier Province during the absence on leave of Lieutenant-Colonel W. R. Edwards, C.M.G. Lieutenant-Colonel H. B. Melville has taken over Medical Charge of the Army Headquarters Staff and Establishments during the absence of Captain A. E. Lister, surgeon to H.E. the Commander-in-Chief. Lieutenant-Colonel J. Penny has been granted an extension of his leave of absence home from India on the recommendation of a medical board.

The services of Major V. Robertson have been placed at the disposal of the Home Department of the Government of India. Major C. Hudson, D.S.O., has been granted 18 months' leave of absence home from India. Major T. B. Kelly has been appointed Specialist in Ophthalmology to the Burma Division. The services of Major H. M. Mackenzie have been placed temporarily at the disposal of the Government of the Punjab. Major R. Brysom has been appointed District Medical and Sanitary Officer at Tinnevelly, and in Medical Charge of the District Jail, Palamcottah, Madras Presidency. Major W. H. Kerrick has arrived home on leave of absence from India. Major A. F. Stevens, civil surgeon at Hazaribagh, has taken up duty as an Officiating Civil Surgeon of the first class during the absence on leave of Lieutenant-Colonel F. C. Clarkson.

Captain W. M. Houston has been appointed Medical Officer, Kathiawar Political Agency, and in charge of the West Hospital at Rajkot. Captain W. C. Long has arrived home on leave of absence from Madras Presidency. Captain M. R. C. MacWatters has been granted furlough for one year. Captain W. D. A. Keys has been appointed Civil Surgeon at Karwar. Captain J. E. Clements has been selected to officiate as Superintendent of the Central Jail at Fategarh during the absence on leave of Lieutenant-Colonel E. Jennings. Captain B. B. Paymaster has been granted leave, combined with furlough, for a total period of two years. Captain W. P. G. Williams has been appointed to officiate as Superintendent of the Central Jail at Bareilly during the absence on leave of Major C. B. Prall. Captain J. Smalley has been appointed to officiate as Civil Surgeon at Dhulia, in succession to Major G. E. Stewart, who has been transferred. The services of Captain C. C. Shaw have been placed temporarily at the disposal of the Chief Commissioner of the Central Provinces. Captain C. E. Bulteel has arrived home on leave of absence from India.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant D'Arcy Power is confirmed in his rank. John William Gray to be Lieutenant (on probation) (dated Dec. 27th, 1911).

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentlemen have been appointed Surgeons (dated Jan. 26th, 1912):—Alfred Ernest Wilson Hird, Alfred Edward Turnbull, Edmund Ralph Sircom, Francis Carminow Doble, Walter Fedde Fedden, James Bruce Ronaldson, Joseph Henry Thompson, William Innes Gerrard, Cecil Brian Forsyth Tivy, and Charles O'Beirne Ryan.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Highland Mounted Brigade Field Ambulance, Royal

Army Medical Corps: Lachlan Martin Victor Mitchell to be Lieutenant (dated Jan. 27th, 1912).

1st East Anglian Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains: Lieutenant Ernest V. Gostling (dated Nov. 6th, 1911) and Lieutenant Gerald M. Hetherington (dated Dec. 23rd, 1911).

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Bernard Richardson Billings, from the List of Officers of the Royal Army Medical Corps attached to Units other than Medical Units, to be Lieutenant (dated Jan. 27th, 1912).

2nd West Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant Owen H. Williams to be Captain (dated Dec. 23rd, 1911).

6th London Field Ambulance, Royal Army Medical Corps: Lieutenant Edward P. Minett is seconded under the conditions of paragraph 114 of the Territorial Force Regulations (dated Jan. 1st, 1912).

1st Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant-Colonel William F. Somerville resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Jan. 27th, 1912). Major George H. Edington to be Lieutenant-Colonel (dated Jan. 27th, 1912).

3rd Wessex Field Ambulance, Royal Army Medical Corps: Lieutenant Frederick E. Stokes to be Captain (dated Nov. 19th, 1911).

4th London General Hospital, Royal Army Medical Corps: Captain Fred. W. Mott to be Major (dated Jan. 27th, 1912).

2nd Southern General Hospital, Royal Army Medical Corps: Captain John Alexander Nixon, from the List of Officers of the Royal Army Medical Corps attached to Units other than Medical Units, to be Captain (dated Jan. 27th, 1912).

4th Southern General Hospital, Royal Army Medical Corps: Lieutenant-Colonel Charles E R. Rendle resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Jan. 27th, 1912).

Attached to Units other than Medical Units.—Lieutenant William J. T. Barker resigns his commission (dated Jan. 27th, 1912).

For Attachment to Units other than Medical Units.—Robert Lowis Routledge to be Lieutenant (dated Nov. 26th, 1911).

Supernumerary for Service with the Officers Training Corps.—The appointment of Lieutenant Henry Stokes (for service with the Royal College of Surgeons in Ireland Contingent, Senior Division, Officers Training Corps) is antedated to April 1st, 1911.

ROYAL ARMY MEDICAL CORPS EXAMINATIONS.

The following is a list of the successful candidates for commissions in the Royal Army Medical Corps at the competition held in London in January, for which 46 candidates entered:—

	Marks.
A. G. Biggam, M.B., Ch.B. Edin., Edinburgh University ...	585
D. T. M. Large, M.B., Ch.B. Edin., Edinburgh University ...	585
W. F. Christie, M.B., Ch.B. Edin., Edinburgh University ...	575
R. K. Mallam, M.B., B.S. Lond., London Hospital	570
W. W. Pratt, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Bristol University	564
*W. B. Stevenson, M.B., B.Ch., B.A.O., Queen's Univ., Belfast, Queen's University, Belfast	544
M. Burnett, M.R.C.S. Eng., L.R.C.P. Lond., St. George's Hospital	543
C. J. Blaikie, M.R.C.S. Eng., L.R.C.P. Lond., St. George's Hospital	540
J. H. M. Frobisher, M.B., B.Ch. Leeds, Leeds University ...	540
C. M. Ingoldby, M.R.C.S. Eng., L.R.C.P. Lond., London Hospital	539
O. W. J. Wynne, L.R.C.P. & S. Irel., Royal Colleges of Physicians and Surgeons of Ireland, University College, London	538
D. T. Richardson, M.B. Ch.B. Edin., Edinburgh University...	534
R. A. Strachan, M.B., Ch.B. Edin., Edinburgh University ...	533
W. McNaughtan, M.B., Ch.B. Edin., Edinburgh University...	525
S. J. Higgins, M.R.C.S Eng., L.R.C.P. Lond., London Hospital and Cambridge University	518
A. Hood, M.B., Ch.B. Edin., Edinburgh University	514
J. L. Ritchie, M.B., Ch.B. Birm., M.R.C.S. Eng., L.R.C.P. Lond., Birmingham University	514
G. A. Blake, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital	503
H. R. L'Estrange, L.R.C.P. & S. Irel., L.M. Rot., Royal College of Surgeons, Ireland	493
*C. J. H. Little, M.B., Ch.B. Leeds, Leeds University	492

* Awarded service marks under Par. 71 of the Regulations for the Officers Training Corps.

INDIAN MEDICAL SERVICE EXAMINATIONS.

The following is a list of the successful candidates at the recent competition for commissions in His Majesty's Indian Medical Service, which was held at the Royal Army Medical College and at the Examination Hall, Victoria Embankment, on Jan. 22nd–27th:—

	Marks.
Ronald Herbert Candy, M.B., B.S. Lond., L.R.C.P., M.R.C.S., London Hospital	3447
Philip John Veale, M.B., B.S. Lond., Bristol University... ...	3376
Henry Hingston, M.B., B.S. Lond., Westminster Hospital ...	3358
Jamasp Cursetji Bharucha, L.R.C.P., M.R.C.S., London Hospital	3338
Frederick Jasper Anderson, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital	3254
Heerajee Jehangir Manockjee Cursetjee, M.B., B.S. Cantab., L.R.C.P., M.R.C.S., L.M. & S. Bombay, Cambridge University and London Hospital	3191
John Simson Stuart Martin, M.B., Ch.B. Edin., Edinburgh University	3094
Peter Fleming Gow, M.A., M.B., Ch.B., D.P.H. St. And., St. Andrews University...	3093
Robert Victor Morrison, M.B., Ch.B. Edin,, Edinburgh University	3019
Joysh Chandra Dey, M.B. Calcutta, Calcutta Medical College	3006
James Walker Jones, M.B., Ch.B. Glasg., Glasgow University	2992
James Hall Hislop, M.B., Ch.B. Glasg., Glasgow University ...	2958

THE ROYAL NAVY LIST.

The Royal Navy List, the 137th quarterly issue of which has just appeared, will appeal to everyone who is interested in naval affairs. To the service and the press it is an indispensable source of reference, while to the public who desire information with regard to the various departments of the Royal Navy—the *personnel*, the ships which form our first line of defence, their names, groupings, and so forth—the book is both valuable and convenient. Compared with the corresponding issue of the List for 1911 the volume is somewhat smaller in bulk, containing only 560 pages, as against 724 last year, but the information which it gives is still characterised by fulness and reliability. In addition to the lists of ships, of officers, and other tabular details, there is a complete history of all the battleships and cruisers of the first and second class, and specially written articles on the "Current History of the Royal Navy" and the "Current History of Foreign Navies," including naval administration and shipbuilding, while there is a chronological list of the notable naval events of the year. One of the most convenient features of the book is the complete alphabetical list of all officers, active and retired, with their services, honours, and special qualifications in the Royal Navy, Royal Marines, Indian Marine, Royal Naval Reserve, Royal Volunteer Reserve, and Australian Naval Defence Forces. The price at which the book is issued—10*s.*—is moderate when the vast amount of information arranged for convenient reference is considered. Messrs. Witherby and Co., of High Holborn and Newman's-court, Cornhill, are the publishers.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of this society was held at 429, Strand, London, W.C., on Jan. 19th. There were present Dr. F. de Havilland Hall (in the chair), Dr. F. C. Martley, Mr. H. P. Symonds, Mr. J. Brindley-James, Dr. G. E. Herman, Dr. W. Knowsley Sibley, Mr. F. S. Edwards, Dr. F. J. Allan, Dr. H. A. Sansom, Dr. F S. Palmer, and Dr. J. B. Ball. The records of the society in the latter part of 1911 have been very satisfactory, comparing favourably with the same period in past years. As usual, in the winter months the claims increase, but so far the amount of sickness experienced has been well within that provided for in the rates of contribution. The time of the committee was largely taken up in examining the list of those who are at present receiving sick pay and who are to all appearances permanently incapacitated from professional work. The society's reserves are large, now amounting to over a quarter of a million sterling, and a considerable portion of this is specially earmarked for the benefit of these chronic cases. Prospectuses and all further particulars may be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

"Audi alteram partem."

FATAL HÆMOPTYSIS IN EARLY LIFE.

To the Editor of THE LANCET.

SIR,—It may interest your readers, in connexion with the cases described by Mr. Carruthers Watt and Dr. Ralph Brown in your issue of to-day and of April 30th, 1910, to refer to a case an account of which I gave to the Pathological Society in May, 1874.[1] It was that of an infant aged 7 months, under my observation at the Brompton Hospital, who had suffered from cough from the preceding Christmas and presented signs of tuberculosis. The cough was spasmodic and attended with a ropy mucous expectoration which had to be removed from the mouth. On April 1st, having had no previous hæmoptysis, the child suddenly expectorated half a pint of dark, partly clotted blood and expired almost immediately. On post-mortem examination the lungs were disseminated with miliary tubercles, and at the base of the left lobe there was a ragged cavity traversed by trabeculæ, some of which contained vessels still patent, and surrounded by tuberculous consolidation. Near the apex of the same lobe there was another smaller cavity of similar characters, across which stretched a vessel one-tenth of an inch in transverse measurement, with thickened walls, but at one point the wall of the vessel was eroded to extreme tenuity and had given way. The vessel was found to be one of the larger branches of the pulmonary artery. Pulmonary tuberculosis is not common at this early period of life, but in this family all the five other children had died in infancy with lung symptoms, the eldest being ten weeks old, and the father was found to be suffering from phthisis.

I believe this to be the first case recorded of fatal hæmoptysis at so early an age, and I classified it as belonging to the third group of the series of cases I had brought before the Pathological Society four years previously.[2] Amongst the 17 cases there recorded the youngest was that of a child aged 14, more fully described by Dr. Symes Thompson in the *Medical Times and Gazette* of May 21st, 1870.

I am, Sir, yours faithfully,

Portland-place, W., Jan. 27th, 1912. R. DOUGLAS POWELL.

THE TREATMENT OF GLAUCOMA.

To the Editor of THE LANCET.

SIR,—I read with great interest the communications by Mr. J. Herbert Parsons and Dr. Leonard Hill to THE LANCET.[3] At the early part of my career I worked for many years at five ophthalmic clinics at the same time—indeed, for ten years. The experience I obtained led me to attach little value to the operative treatment of those cases in which one rarely if ever found increased tension—i.e., tension detectable by palpation. That the blocking of the angle was the determining cause of glaucoma in these cases did not appeal to one's judgment, and especially in view of the fact that some even with *deep cupping* retained their sight for many years under purely drug treatment. At the Ophthalmological Society I have several times emphasised the hypothesis that, given toxins or antitoxins or any such irritant in any amount for a considerable time, tension would result from swelling of the epithelium cells, and especially those lining the canal of Schlemm. So firmly did I believe this to be the case that my treatment for many years has been largely conservative. Not long ago I was called to see a feeble patient with acute glaucoma. In this case medical treatment was tried: (*a*) gutt. eserin. gr. 1 saepe until the pupil contracted; (*b*) a brisk purgative; (*c*) diminution of the supply of fluids; and (*d*) the placing of the patient in the cardiac position, &c. The patient made a perfect recovery and during the last two years under suitable drug treatment has had no further symptoms. Dr. J. Stewart Richards, of Croydon, kindly undertook supervision of the case.

As regards chronic glaucoma with rare attacks of tension and very deep cups—i.e., in precisely the cases in which operation is apt to result in rapid contraction of the field of vision, and in which operative treatment most signally fails—I have had results well worth recording. One case, a myope with advanced glaucoma, deep anterior chambers, and only occasional tension, vision was kept at or about 6/12 with correcting glasses for 15 years. During my holidays she had attacks of fog, for which iridectomy was done by one of the most expert operators in London, with the result that in a few months she was quite blind. In a second case, a lady with very deep cups was advised by an eminent oculist, to whom I sent the case for an opinion, to submit to an immediate operation. I saw her a few days ago. Vision in the right eye is 6/18 and in the left 6/12 good and 6/9? The field in the right eye is badly contracted on the nasal side but good in the left eye. It is now 20 years since my eminent *confrère* recommended immediate operation.

Another interesting case which tends to bear out Dr. Leonard Hill's teaching was that of a man with subacute glaucoma and cloudy cornea. On this man I performed an iridectomy on the worse eye, but it resulted in no benefit whatever. I accordingly induced a friend, who very deservedly enjoys a great reputation for operative skill, to see him. He inspected my iridectomy wound very carefully and declined to operate on the other eye which was similarly affected. As treatment seemed useless—i.e., the treatment by eserine—and the man persistently came to my out-patients despite all efforts to discourage him, I determined to put him on active mercurial treatment. The result was an apparent cure, and he retained his sight in the unoperated eye for about nine years—indeed, until the time of his death. Of course, I have lost scores since then, but these cases show the necessity of taking Dr. Leonard Hill's teaching very seriously. My own conviction is that iridectomy for chronic glaucoma should never be relied on without attention to certain details which will appear lower down. As regards the newer operations, I incline most to that of Major Herbert on the ground that, despite his belief, sections recently made prove that filtration can take place through the new tissue. There is an even greater probability of success if we can delay healing in such a way as to produce a permanent fistula, which seems by no means an impossibility if time is allowed for epithelium to grow up along the track of the knife. To estimate these operations in glaucoma, such as I have referred to, it is idle to suppose they have been successful on the ground the vision and fields remain stationary for merely a year or two.

The treatment I now follow is to show the patient the kind of halo seen in glaucoma, and instruct him to look for it at night before retiring (as there is very properly a suspicion that the attacks of tension occur at night), and in the event of there being even a suspicion of such a halo to instil gutt. eserin. gr. 1-8th. The patient is further instructed to sleep in the cardiac position. Very urgently are all glaucoma cases advised not to sleep with the pillow pressing on the great veins of the neck. These injunctions are also given to those suffering from iritis, as in no cases do we see the result of such pressure more acutely felt; indeed, the pressure of the pillow seems to be quite a common cause of the exacerbation of pain at night when in bed. Another precaution one takes is to give a small dose of hydrarg. last thing at night on the supposition that it may help to restrain the growth of bacteria in the alimentary canal. The bowels are washed out every ten days or so with a brisk saline. My experience of this treatment has been such that one would be reluctant to give it up.

I certainly hope that Dr. Leonard Hill's paper will be widely read, as he undoubtedly gives us a good scientific basis to work upon.

I am, Sir, yours faithfully,

CHAS. WRAY, F.R.C.S. Eng.

Victoria-street, S.W., Jan. 26th, 1912.

To the Editor of THE LANCET.

SIR,—It affords me satisfaction to have obtained from Dr. Leonard Hill a statement of his own opinions on the subject of glaucoma, partly because I could not believe that Dr.

[1] Pathological Transactions, vol. xxv., p. 39.
[2] Ibid., vol. xxii., p. 55.
[3] THE LANCET, Jan. 6th (p. 15) and 27th (p. 226), 1912.

Thomson Henderson's writings gave an adequate expression of those opinions, but chiefly because it is only by enlisting the active interest and coöperation of physiologists that advance in our knowledge of the physiology and pathology of the intra-ocular pressure can be attained. I have so profound a respect for the views of those who are *au fait* with the latest researches in physiology that any criticism of Dr. Hill's remarks which I venture to offer are put forward in the rôle of *advocatus diaboli* rather than that of confirmed antagonist. The statement which Dr. Hill controverts is founded upon the experimental work of Leber, Starling and Henderson, myself, and others. I have always been careful to state that the physical conditions of the formation of lymph "are consistent with" or are "not inconsistent with" its production by a process of filtration, for I have never brought myself to believe that the living endothelial cells which form the walls of the capillaries and the retinal epithelial cells which cover the ciliary processes play a merely passive part in the production of the intra-ocular lymph. Such experimental work as I am familiar with appears to me to support the statement in the terms which I have used, and the deduction that there is a difference in pressure on the two sides of the capillary walls is thus far justified. The bald statement that "there is *no* evidence which demonstrates that there is a hydrostatic difference of pressure on either side of the capillary wall" does not under these circumstances carry conviction. Dr. Hill apparently admits the physical process of filtration in the absorption of lymph, for he says that "each pulsatile expansion in the arteries of the eye helps to drive a little of the aqueous into the efferent veins."

With regard to Martin Fischer's work, it appears to me to be as risky to apply such results obtained upon the excised eye directly to the living eye as it is to make deductions from a mechanical model. We know that an excised frog's muscle will take up water from strong saline solutions against osmotic pressure; it does not follow that the living muscle will behave in the same manner, and in fact it does not. The statement as to the action of sub-conjunctival injections in glaucoma has unfortunately been amply disproved. The suggestion, however, that the swelling of colloids is an important factor in glaucoma opens up a wide field for research, and if any remarks which I have made stimulate physiologists to direct their attention to the subject I shall be well repaid for any errors of which I may have been guilty. I am, Sir, yours faithfully,

J. HERBERT PARSONS.

Queen Anne-street, W., Jan. 29th, 1912.

THE PROPAGATION OF PLAGUE WITHOUT THE AID OF INFECTED RATS.

To the Editor of THE LANCET.

SIR,—I have perused with considerable interest your leading article on this subject in THE LANCET of Dec. 16th, 1911. I beg to forward, under separate cover, a copy of my paper on Plague published in the *American Journal of the Medical Sciences* in September, 1909. I have tried therein to represent the views upon pneumonic plague which are held here, and which have been amply borne out by my clinical experience, now extending over 15 epidemics in this city. Whilst fully agreeing with Dr. R. Farrar as to direct infection in the propagation of pneumonic plague, there are other possible channels of infection that should not be overlooked, as you will find pointed out on p. 14 of my pamphlet. Should the apparent primary pneumonia be but a result of septicæmia, then the intervention of the flea would be necessary, whether the tarabagan or the human flea, I am not prepared to say. The sequence of events would then stand thus: (1) Infected tarabagan; (2) infected flea of same; (3) human infection, with rapid and early septicæmia followed by (4) pneumonia, *apparently* primary, but really secondary to blood infection.

As regards the sputum infecting from secondary pneumonia in a case of bubonic plague, the chances of infection are infinitesimal, though the probability could hardly be denied. The complication is comparatively rare, and the sputum not generally free or abundant. I have not come across any instances of infection in this way throughout my long connexion with the disease.

I am, Sir, yours faithfully,

Bombay, Jan. 6th, 1912. N. H. CHOKSY, M.D.

THE MORBID DIATHESES.

To the Editor of THE LANCET.

SIR,—My esteemed former house surgeon, Mr. MacIlwaine, credits me with little knowledge of the writings of my revered teacher, Dr. Moxon, and proceeds to contend against conclusions presumed to be in my Bradshaw lecture without apparently having read that address. My argument in reference to the diatheses was that many diseases formerly dogmatically taught to be due to hereditary constitutional causes, such as tubercle, leprosy, malaria, rheumatism, had been proved by modern investigation to be due to the in-roads of micro-organisms, or, to use the terms of our common teacher, had been removed from the intrinsic to the extrinsic class. Nowhere do I deny that disease may not commence from defects in the organisation of any individual. But Mr. MacIlwaine's illustrations are not all well chosen; for nothing is more certain than that attacks of asthma may be caused by the pollen of certain plants and the odours of various animals, and "chronic lunacy" is certainly not always dependent on a constitutional cause, for that form of chronic lunacy which is associated with general paralysis has been most clearly proved to be due to the degenerations caused by the ravages of the spirochæta pallida.

I am, Sir, yours faithfully,

Wimpole-street, W., Jan. 30th, 1912. R. CLEMENT LUCAS.

ELECTRIC METALLIC COLLOIDS AND THEIR THERAPEUTICAL APPLICATIONS.

To the Editor of THE LANCET.

SIR,—I have read with great interest M. Duhamel's article on the use of metallic colloids in medicine in THE LANCET of Jan. 13th. I was unaware that so much work had been done with this comparatively new therapeutic agent. M. Duhamel is undoubtedly an authority on this development of treatment in clinical medicine, but I think he is not justified in sweeping on one side all colloids of metals produced by chemical means as useless, and asserting that those produced by electrical means only are of value.

The new metallic colloids of silver and mercury recently introduced by Mr. Henry Crookes, under the name of "collosols," are made by an entirely novel chemical reaction and produce metallic colloids which are eminently stable and of great Brownian and bactericidal activity. The particles are of very small size and of perfect uniformity as seen under the ultra-microscope. It has also been found that when injected into the blood stream the particles do not block the capillaries. These collosols have been reported on by Professor Emil Hatschek as being "well made, free from reduced mercury and silver salt, and sufficiently stable towards electrolytes, heat, and the influence of organisms for all reasonable requirements." Mr. Crookes's collosols are made of a standard strength, namely 500 parts of metal to 1,000,000 parts of liquid—i.e., 1 in 2000. Laboratory experiments over a considerable period of time show that all bacteria experimented with are killed rapidly by one or the other of these collosols. The strength may be reduced to as little as 5 or 10 parts per 1,000,000, and in some cases as little as 1 part of silver per 1,000,000 has proved fatal to the bacteria in a few minutes. The bacteria experimented with were *B. coli communis*, *B. tuberculosis*, *diplococcus gonorrhœæ*, various forms of *staphylococcus* and *streptococcus*, and many others. The collosols are practically tasteless, of a reddish-brown colour, perfectly clear by transmitted light, and fluorescent by reflected light. They may be applied topically, hypodermically, intravenously, or by the mouth, and being non-toxic the dose hypodermically is unlimited, and experimental injections of 1 to 2 c.c. give little or no local or reactionary symptoms. It is necessary, of course, when giving hypodermically or intravenously that proper and usual precautions be taken. My own clinical experience with these chemical colloids during some months of recent practice entirely corroborates that of M. Duhamel with the electrical colloids, and I have treated the following cases with marked and surprising success. *Topically:* Septic and follicular tonsillitis, Vincent's angina, phlyctenular conjunctivitis, gonorrhœal conjunctivitis, spring catarrh. Impetigo contagiosus, acne of face and body, septic ulcers

of legs, ringworm of body, tinea versicolor. Soft sores suppurative appendicitis after operation (the wounds cleaned rapidly). Pustular eczema of scalp and pubes, chronic eczema of external meatus of ear with recurrent boils, and also chronic eczema of anterior nares. Offensive discharge in case of chronic suppuration in otitis media, bromidrosis of feet and axillæ. Blind boils of neck. *By injection:* Gonorrhœa and chronic cystitis (local), boils, epididymitis. In above cases I found that symptoms were relieved rapidly.

In these circumstances I feel justified in asserting that "collosols" are quite equal to, in their clinical action, if not better than, electric colloids, and my object in writing this letter is to bring before the medical profession the advantages that can be gained in treatment by the use of chemical collosols.

I am, Sir, yours faithfully,

C. E. ALEX. MACLEOD, F.R.C.S. Eng.

Ladbroke-grove, W., Jan. 24th, 1912.

SALVARSAN AND SYPHILIS.

To the Editor of THE LANCET.

SIR,—My first experience of salvarsan was in September, 1910, at the Hôpital St. Jacques, Brussels. The results observed there were quite brilliant, but in many cases the swelling caused by the injection was of the size of a clenched fist, exceedingly painful to the touch, and attended by great pain lasting often three days. One injection was made deeply into the muscles of the back.

Most of the writers on this subject in your columns have specially commented upon the painfulness of this procedure. Salvarsan, I think, is not very irritating or caustic to the tissues if properly prepared, but the sudden introduction of 10 c.c. of any powder in suspension which is not immediately absorbed must produce tension and consequently pain, even if not more serious consequences, such as necrosis and sloughing.

I have been using salvarsan ever since it was procurable on the market, and have employed it in the following manner. The emulsion is prepared at the side of the bed with all aseptic precautions. The patient lies on his stomach; both buttocks and the skin below both scapulæ are painted with tincture of iodine. Into each of these sites the emulsion is injected in about equal quantities. The needle of the syringe is necessarily somewhat large and four injections are more disagreeable than one, but any after-pains have in my cases been negligible, therefore opium has never been required either before or after the injection. Practically there has been no rise in temperature. The dose given has been 0·6 gramme except in the case of children.

All must, I think, admit the speedy and remarkable results of this drug in many forms of syphilis, but at the same time we are all familiar with the rapid improvement which takes place in some syphilitic lesions by the administration of large doses of the iodides.

Last year I saw in the Hôpital St. Louis, Paris, cyanide of mercury given intravenously; it caused not the slightest inconvenience to the patients, and benefited wonderfully the specific lesions. To produce rapid results it seems necessary to administer a powerful poison to the treponema, and excellent results follow the intensive treatment by mercury urged by M. Jacquet, which I have been using for some time. We must all be grateful for the addition of "606" to our weapons against the devastating action of syphilis; the dream of Ehrlich has yet to be fulfilled, though he has materially helped its consummation—the discovery of agents parasitotropic, but not organotropic, when administered in disease.

I am, Sir, yours faithfully,

Wigan, Jan. 23rd, 1912. R. PROSSER WHITE.

RESEARCH DEFENCE SOCIETY.

To the Editor of THE LANCET.

SIR,—It is just four years since this society was founded to make generally known the facts as to experiments on animals in this country and the regulations under which they are conducted, the immense importance of such experiments to the welfare of mankind, and the great saving of human and animal life and health which is already due to them. We hope that you will kindly allow us to report progress. During the past year the society has gained 1000 new members and associates and has formed ten new branches. It now has 5000 members and associates. During the year the society has lost by death eight of its vice-presidents—Sir Henry Butlin, Canon Duckworth, Lady Foster, Dean Gregory, Sir Joseph Hooker, Dr. Hughlings Jackson, the Bishop of Oxford, and Sir Samuel Wilks. The following have consented to act as vice-presidents: H.H. the Aga Khan, Mr. Waldorf Astor, Mr. Otto Beit, Lord Cobham, Lord Dunedin, Lord Leconfield, Sir Henry Morris, the Bishop of Rangoon, the Bishop of St. Asaph, Mr. Paul Swain, and the Bishop of Truro.

The following pamphlets and leaflets have been published during the year: (1) A Question of Ethics; (2) Experiments during 1910; (3) The Facts of the Case; (4) The Saving of Human Lives; (5) The Rockefeller Institute; (6) The Case presented by Antivivisectionists; (7) Recent Surgical Progress; (8) Antivivisection Shops; (9) Tuberculosis: (10) Sleeping Sickness; (11) Annual Report, Balance Sheet, and List of Members and Associates. A book is in the press, giving a full *résumé* of the evidence before the Royal Commission. It will be published within a few weeks after the publication of the final report of the Royal Commission.

Since Jan. 1st, 1911, the number of addresses, lantern lectures, and debates has been about 120. The quantity of literature which has been distributed has far exceeded that of any preceding year. The society has held stalls at various important exhibitions.

We greatly hope that many of your readers will become members or associates of the society, and will help its useful work. The hononary secretary will always be glad to answer every inquiry, to send literature to all applicants, to receive names for membership or associateship, and to make all necessary arrangements for addresses and lantern lectures in London or elsewhere.

We remain, your obedient servants,

CROMER, President.
SYDNEY HOLLAND, Chairman of Committee.
F. M. SANDWITH, Hon. Treasurer.
STEPHEN PAGET, Hon. Secretary.

21, Ladbroke-square, London, W., Jan. 27th, 1912.

MICHEL'S METAL SUTURES IN GASTRO-ENTEROSTOMY.

To the Editor of THE LANCET.

SIR,—Any detail about this valuable operation seems worth considering if time can be saved in making the junction between the stomach and the bowel without any loss of security. Murphy's buttons and time-saving apparatus such as the newly invented sewing-machine are now not often used. Most surgeons, I think, make a double row of stitching. But the interior row after the openings have been made in the stomach and bowel can be securely and quickly made by metal suturing. This procedure I have tried only in one case of gastro-jejunostomy in a patient exhausted and emaciated with cancer of the stomach and it proved perfectly successful. There is no need to point out the mechanical advantages of metal sutures or the rapidity with which adaptation can be effected. The small teeth are bitten together after use and a thin light ring results which should do no more harm than any other unabsorbable fixation. A metal suture takes a larger surface area of approximated tissue than does a stitch and a row of metal sutures is very light and flexible.

Mr. Moynihan's interesting paper on Jejunal Ulcer in the *Universal Medical Record*, p. 11, suggests remote injurious results from the use of unabsorbable ligatures and quotes Wilkie;[1] the presence of an unabsorbable suture in the granulation area tends to delay repair. Moynihan remarks that the evidence is "perhaps a little slender." Whether other surgeons have tried metal sutures in gastro-enterostomy I do not know, experience will encourage or discredit their use. We must be cautious in writing of any ligature as unabsorbable, for time, *edax rerum*, makes many substances soluble, and solubility has its peculiar dangers from mechanical, toxic, and chemotaxic causes.

I am, Sir, yours faithfully,

GEORGE WHERRY, M.C. Cantab., F.R.C.S. Eng.

Cambridge, Jan. 26th, 1912.

LOCAL REACTION IN TUBERCULIN TREATMENT.

To the Editor of THE LANCET.

SIR,—I was much interested in the remarks of Dr. H. W. Godfrey in THE LANCET of Jan. 20th, p. 194, with reference to the treatment of pulmonary tuberculosis with tuberculin. I am quite in agreement with him when he says that many cases are unsuitable for tuberculin treatment, and also with his remark that those which are suitable should be treated correctly; our difficulty is to know which is the correct method of treatment. There appear at present to be two ways of treating the disease; by one method a cure is attempted by stirring up the bacilli at the seat of disease, and the other by preventing the disease from ever becoming active in any way again. The first method can be accomplished by giving exercise and by giving tuberculin in sufficiently large doses, the second by rest and giving sufficiently small doses of tuberculin, in individuals who are apparently able to transform the injected tuberculin into some anti-substance before it reaches the diseased focus in the lung. Both methods in some cases produce cures. The latter method has, however, this advantage, that it is not dangerous, which cannot be said of any method that may cause renewed activity of the disease in such an organ as the lung. When possible, therefore, I have been accustomed for the last 12 months to attempt to produce a local reaction at the site of inoculation and none at the seat of disease. In this effort, in suitable cases, I have been quite successful, and have noted that when the local reaction has been severe the only symptoms following are beneficial, resulting in falling temperature, immediate diminution of sputum, increase in appetite and weight, and no increased activity at the diseased focus in the lung. Even with care one is liable to overshoot the mark and produce some focal reaction, but if a rectal temperature be taken, this can be perceived at once, and the next dose reduced in amount.

I first noticed local reactions when I began giving tuberculin in 1909. I am aware that Carl Spengler has given tuberculin injected into the forearm, but the reason for this being done in my cases was at first simply on account of convenience. Subsequently, when visiting other sanatoriums to study the question, I found that it was difficult to follow local reactions when the injections were made into more fleshy parts. However, so much has been written upon tuberculosis that it is almost impossible to read everything—indeed, if one does, the result is only likely to produce a feeling of incompetence in oneself, or to tempt one to go from treatment to treatment whilst the patient is getting worse. I have no particular wish to claim any originality in the matter, for if I really knew, I have no doubt someone else has pointed out that *with a severe local reaction it does not necessarily follow there will be any focal reaction*, and this, together with the necessity of taking a rectal temperature (a method I first learned to appreciate through the kindness of Dr. H. G. Felkin, of the Linford Sanatorium), are the matters which I wish to lay stress on, the most important temperature being that taken before rising in the morning.

I am, Sir, yours faithfully,

Ayrshire Sanatorium, Jan. 22nd, 1912. EDWARD E. PREST.

PSYCHOTHERAPY AND GENERAL MEDICINE.

To the Editor of THE LANCET.

SIR,—May I have space for a brief answer to Dr. E. Ash's letter on the above-named subject in THE LANCET of Jan. 27th?

1. Dr. Ash complains because I applied the word "chicanery" to the methods of bald suggestion. The word was certainly ill-chosen, and I withdraw it; for it imports not only deception but unworthy deception, and this last I did not intend to imply. For the rest, I conceive that when a man surrenders his judgment to another and accepts without criticism whatever he is told, then he is allowing himself to be imposed upon, even though the imposition be practised for his advantage. It was in the sense of such deception as this that my remark was meant; and I was far from wishing to asperse the integrity of those who employ direct suggestion.

2. Dr. Ash considers that what I described as "rational psychotherapy" is equivalent to "psycho-analysis" done badly. This is not the case, however, and I should be sorry if the two were at all confounded. For what I described is at the worst harmless, while I doubt whether so much can be said for the other, presuming that the method of Freud is the one indicated by my critic. Psycho-analysis seeks (by methods which do not commend themselves to me) to unearth past emotions which, though long since forgotten and lost to consciousness, are yet capable, so it is said, of perpetrating mischief upon the patient. There is nothing so abstruse or dubious about the proceeding I urged, which, from the diagnostic side, amounts to little more than this: that one should be on the look-out to detect the occasions on which a patient consciously withholds from the doctor his ill-founded but damaging apprehensions of physical disease, while he emphasises to a deceptive extent the symptoms upon which those apprehensions are based.

3. Dr. Ash credits me with claiming that "rational psychotherapy" is immeasurably superior to direct methods of suggestion. I am pretty sure that no such claim can be read into the article with justice. For I was at pains to write with the moderation demanded both by my own experiences of the method I wrote of and by my ignorance (correctly surmised by Dr. Ash) of the practice of direct suggestion. It does, indeed, seem to me axiomatic that of two methods, one of which appeals to reason and the other (frankly) to something quite remote from reason, the former is likely to be the more healthy for the patient, and should be chosen if possible. But the choice is not always open, and I can imagine well that many patients who are beyond the reach of "rational psychotherapy" might be amenable to the methods of my critic. They will be, however, people whose loss of mental equilibrium is more profound than is the case with the classes of invalid to which my article referred, the latter being typified by the common run of patients who attend the medical practice of a general hospital, not those who are hovering between the neurologist and the alienist.

4. It is undoubtedly true, as your correspondent says, that an element of direct suggestion enters, in practice, into "rational psychotherapy," but this fact does not seem to me to stultify the essential objective of the method, which is to appeal to the patient's reason.

I am, Sir, yours faithfully,

WILLIAM P. S. BRANSON.

Devonshire-place, W., Jan. 28th, 1912.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—I was glad to see the able letter of Dr. E. T. Larkam in THE LANCET of Jan. 27th. He goes to the whole root of the matter when he says that independence is the primary and essential requisite for our profession. We should all urge this as our first principle, and be satisfied with nothing less. What good are the "cardinal points" if they are under the control of—and administered by—committees composed chiefly of adherents of un-Friendly Societies? "That were low indeed, That were a shame and ignominy beneath this downfall"!

I am, Sir, yours faithfully,

Winchester, Jan. 29th, 1912. W. HARMAN.

To the Editor of THE LANCET.

SIR,—At a meeting of the council of the British Hospitals Association on Jan. 18th the following resolution was unanimously carried:—

The British Hospitals Association is strongly of opinion that upon the Insurance Act coming into force insured persons, except for accidents or sudden emergency, should no longer be received in the out-patient or casualty departments unless accompanied by a certificate or introduced personally by the medical practitioner who is in attendance, and in such a case after consultation he should be referred back to the same medical attendant, with an expression of the opinion of the hospital physician or surgeon on the case.

And that a list of all such insured persons, and the practitioners by whom they are sent, should be forwarded to the Insurance Committees of the district periodically.

With regard to the in-patients, the council are drawing up

a general statement for the information of members of the association upon the bearing of the Insurance Act on the in-patients, which will be sent out shortly.

I am, Sir, yours faithfully,

A. WILLIAM WEST.
Chairman of Council.
E. STEWART JOHNSON,
Hon. Treasurer.
DONALD J. MACKINTOSH,
Hon. Secretary.

Jan. 24th, 1912.

To the Editor of THE LANCET.

SIR,—In deciding the mode of payment to be adopted do not let us forget the ever recurring epidemics of influenza and the appalling amount of extra work thereby incurred for which hitherto we have never received an extra penny from the so-called Friendly Societies. In rural districts these epidemics are much to be dreaded. Since the beginning of the year I have scarcely had a spare moment owing to this disease.

I am, Sir, yours faithfully,

T. CUMING ASKIN, M.D. Dub.

Alderton, Woodbridge, Suffolk, Jan. 29th, 1912.

To the Editor of THE LANCET.

SIR,—It has been decided to hold a special Representative meeting of the British Medical Association on Feb. 21st in order to determine the position that the Association is to take up with regard to the National Insurance Act. It is generally recognised that the decisions come to at that meeting will have a momentous effect on the practices of present members of the profession, on their successors, on the advance of medicine, and ultimately on public health. It is, therefore, most desirable that those medical practitioners who propose to instruct these Representatives should be conversant with the actual details of the Act and not allow their minds to be swayed by side issues.

No better means could be found for placing medical constituents in a position to give sound instructions than for them to use the interval, before they have to come together in a Division meeting of the Association, to hold several small informal meetings amongst themselves. These meetings need not be of long duration, should not be made an excuse for speeches, but rather should be educational in their aim and devoted to an exchange of ideas. They could be arranged by any member inviting those in his immediate neighbourhood to discuss the subject with him. Possibly it might be desirable to hold a separate meeting for the consideration of certain subjects, and so to limit the range of discussion on each occasion. Subjects that suggest themselves are the relation of the Act to (1) club practice; (2) private practice; (3) charitable medical services; (4) existing State medical services. It would prove useful if before attending these meetings each practitioner were to read through the following sections of the Act: Sections 1; 8; 10 (1); 11; 12; 14 (1), (4); 15; 16; 17; 18 (1); 19; 20; 21; 37 (1) (*a*); Schedule 4, Part 2; 42; 45 (1) (*d*); 46 (2) (11), (3) (*f*), (3) (*h*); 48 (12); 51 (*i*); 57 (1); 58; 59; 60 (1) (1); 60 (2); 61 (1) and (2); 62; 63 (1); 64 and (2); 65; 69 (1); 78; 83.

Were hundreds of such informal meetings held throughout the United Kingdom during the next few days there would be less heard in the Association of demands for an amending Act, when all that could possibly be required is obtainable in the Regulations (see Sections 65 and 78); of the incompetency of the electors to instruct their Representatives; and of the failure of these Representatives to deal adequately with the situation created by the National Insurance Act.

I am, Sir, yours faithfully,

Jan. 28th, 1912. SPECTATOR.

ROENTGEN SOCIETY.—A meeting of this society will be held on Tuesday next, Feb. 6th, at the Institution of Electrical Engineers, Victoria Embankment, London, W.C., at 8.15 P.M., when a paper on After-glow in Vacuum Discharge Tubes will be read by the Hon. R. J. Strutt, F.R.S. The honorary secretaries are Dr. F. Harrison Low, 13, Wimpole-street, W., and Dr. Robert Knox, 7, Harley-street, W.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

Motor-car Licences.

UNDER the Finance (1909–10) Act, 1910, Section 86 (4), it is provided that if any motor-car is kept by a medical man for the purpose of his profession, he shall be entitled to an allowance in respect of the duty payable under this section on the licence for the car equal to half the amount of duty so payable. Practitioners claiming this should ask at any post office for Form No. 1A, and fill in that form instead of the usual Form No. 1. In London this form, together with the duty, should be sent direct to the Comptroller, London County Council, 23, Cockspur-street, S.W. In other counties this form must first be certified by the local licence authority.

The 12 h.p. Rover Car.

For many years the Rover Co., Limited, of Meteor Works, Coventry, and New Oxford-street, London, W.C., have enjoyed, especially among doctors, the best of reputations, and deservedly so, on account of their excellent 6 and 8 h.p. cars, which many of the profession have run with success, and, what is more, disposed of at very good prices when their "motor fever" had become more acute and they had decided to buy a larger and more powerful car. The one point which I believe proves, more than anything else, the reputation of a car is the value that a second-hand one fetches, and I have heard of a Rover which, after six months' use, fetched within 20 per cent. of its original cost.

A particular aspect of the new Rover Car is that it is fitted with a Silent Knight engine, which is made at the Meteor Works under the same patents as those of the Daimler, Panhard, and Minerva Companies. The fact that so many firms have adopted slide valve engines, and that the Daimler Co. have now sold them for some three years, is unquestionably a proof that the type answers, "F.R.C.S. Eng.," writing in THE LANCET of July 8th last year (p. 124), states that he ran a 15 h.p. Daimler fitted with this type of engine 5203 miles in a year, and that the only mechanical breakdown in that period was caused by the fracture of a ball race. Yet I do like the old poppet valve engine, and when anyone holds forth too enthusiastically on the other I always think that, if the inventions had come in the reverse order, the originators of the poppet type would have proclaimed the simplicity of the poppet over the slide valve.

The engine of the new 12 h.p. Rover is a two-cylinder one, bore 96 mm., stroke 130 mm., which means to doctors a tax of £1 11*s.* 6*d.* Except that it has only two cylinders, it is similar in construction to the four-cylinder Silent Knight Daimler described on p. 1025 in THE LANCET of April 15th, 1911. The oil-troughs under the big ends of the connecting rods have not a variable depth. The oil is pumped from the sump to the receptacles beneath the big ends, which are fitted with scoops. These pick up the lubricant as the engine revolves and splash it on to the pistons, sleeves, and bearings, when it passes through a gauze back to the sump. All that is required is to fill up with oil until it escapes from an overflow tap. Two small pumps convey the oil to the troughs, and a third pump, by a pipe outside the crank-case, with a branch to an indicator of large size on the dash, conveys oil to the worm-gear driving the water-pump and magneto. An adjusting screw to regulate the supply is fitted near the crank-case, so there is no possibility of any oil leaking on to the dash, which is a common occurrence when it is placed near the drip. As long as oil passes through the indicator the lubrication is complete. As the combustion heads are machined, pre-ignition from carbon deposit in these particular places is unlikely to occur; but if there is excessive over-lubrication the piston head may become sooted, and so cause explosion of the mixture prior to complete compression. On these cars the cylinder heads can easily be removed, and thus any deposit of burnt oil may be scraped away. This, however, should not be needed more than once in two years, and perhaps not even then if the lubrication is correctly adjusted.

The carburettor is of the two-jet type, and gives the fullest power of which the engine is capable. It has—what I believe is the one important feature that all carburettors should possess—a jet which can be easily taken out. A

satisfactory petrol filter is fitted. The water is circulated by a centrifugal pump driven by worm-gearing, and has the advantage that, should by any possibility anything happen to it, there is still a clear passage for the cooling fluid to pass properly. The radiator is of the honeycomb pattern, and is attached to the frame by hinges, so that road shocks are not likely to cause it to leak. A fan is fitted behind, but the circulation is so efficient that the makers recommend running without it in winter. The ignition is the Bosch duplex, consisting of a high tension magneto and a small and compact switch and coil, which latter is in connexion with the primary winding of the magneto, the effect of this being that by the aid of a four-volt battery the output of the magneto is increased by self-induction, and at even very low speeds a strong spark is induced, and the engine can always be easily started. The coil is not intended for continuous running, and when the engine has started the switch should be turned over to the magneto position. The clutch is of the flat metal plate type, consisting of the main clutch body, two steel and three phosphor bronze plates, and a back compression ring operated on by three levers, which are either compressed or released by means of the clutch spring or clutch pedal respectively. It can be easily removed without taking down the gearbox or engine, and runs practically dry. All that is needful when reassembling the plates is lightly to smear them with oil.

Opinions, I know, differ as to whether a leather-faced cone clutch or a multiple disc is the best. Personally, I believe that either, if well made, acts equally well, and certainly the Rover type of the latter is well made, grips well without being fierce, and on the test I gave it certainly the multiple disc was ideal. The gearbox is fitted with a gate change, and the change speed levers and quadrant are connected direct to the gearbox by means of an aluminium casing, so that any slight movement in the frame, due to road shocks, cannot affect the change speed, which I found always to work easily and smoothly. Three speeds forward are provided, and though I know there are many advocates of four it seemed to me that three are ample for a car of this power. All the gear shafts run on ball bearings. Between the clutch and the gearbox the coupling takes the form of a double universal joint, one-half of the star variety, the other of the sliding block kind, which permits of the movement required to withdraw the clutch. A flexible union like this appears undoubtedly to have an advantage over what is known as the unit system, in which the engine and gearbox are either made in one piece or are bolted together so that they are solid. The final drive is by an encased propeller shaft, with a ball type universal joint at the front end, to a worm drive back axle, with the worm on top of the worm wheel. This gives greater clearance, and gets the whole of the transmission from the engine to the back axle in line, a method that gives longer life to the universal joint. Those who fit the worm below ignore the wear their method entails on the universal joint, and claim that the freedom they obtain from bed wear compensates. In a well-supported worm, such as on this car, the fear of bed wear may, however, be disregarded. Both brakes are applied directly to the back wheels, and are of the internal expanding variety, the expanding segments taking effect upon concentric drums, the hand-worked one acting on the smaller drum, and the pedal controlled one on the outer. It certainly does seem a great advantage that the brake strain is direct and not conducted through the gears, as is the case with the ordinary propeller-shaft brake.

The springs are semi-elliptical. Daimler pattern supplementary coil springs are fitted to the back of the rear springs, which are really shock absorbers, and make the springing of the car most luxurious, eliminating the evil effects arising from unevenness of road surface, and thus doing away with slipping between the tyre tread and the road, and effecting a saving in the wear of the tyre. I understand that on these cars as much as 8000 miles can be had out of the back tyres. A small but useful refinement is that the spring ends and shackles are fitted with greasers, and if these are but kept replenished the rattle which occurs in so many cars at these points should be avoided. The petrol tank is on the dash and is filled from inside the car. The undershield extends back to the gearbox. The tyres are Dunlop 810 mm. by 90 mm.

The standard body is flush-sided, of a torpedo type, and is ideal for the profession. With the hood up ample protection is given in all kinds of weather, and the scuttle dash and high side doors are certainly a great improvement on the old pattern type of body which left the front seat occupants so exposed to the elements. I would suggest, however, that in hot weather a ventilator might be fitted, as the heat from the engine makes the front compartment rather close and hot.

I spent a morning in visiting patients and in driving over all the villainously bumpy roads I could find—and Kent still boasts a few—and yet we travelled wonderfully comfortable. Most hills were easily climbed on second speed, and only on hills such as Willenhall-road, Woolwich, 1 in 5, was the first needed. Both in the open country and in traffic the car was simplicity itself to drive, and in addition, whether crawling through Victoria-street, Westminster, or at high speed over Dartford Heath, the engine sensation was of the smoothest, and the pull continuous and regular. I have seldom handled a car which gave more pleasure to drive, and I can certainly strongly recommend it as a suitable mount for medical men.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Drainage Scheme.

THE city surveyor, Mr. T. de Courcy Mead, on Jan. 22nd, in a lecture on this subject, said that a hundred years ago the open country was within a few minutes' walk from any part of the town. The inadequacy of the present system of sewers was well known, hence the scheme to provide better sewerage arrangements. Manchester was incorporated in 1838, and in 1853 the borough was constituted a city. In 1885 the area was enlarged from about 4300 acres to about 6000. In 1890 the area reached 13,000 acres, and by other additions in 1909 the area was increased to 21,643 acres, more than five times the original area. In the same period the population increased from 222,120 to 695,173, or three times the population of 1838. The present population is 714,427. The Mersey and Irwell Joint Committee was established in 1891 to enforce the provisions of the Rivers Pollution Prevention Act, 1876. Already the sum spent under its jurisdiction is about £6,070,000, and the population in the area supervised is 2,782,215. An effluent of a high standard of purity is necessary where large volumes of sewage are discharged into a canal, as is the case in Manchester. The new works, for which Parliamentary sanction has been obtained, will cost about £1,000,000, which will be met by a loan payable over a period of 50 years. When completed the drains will be of sufficient capacity to take the sewage from an area of 60 square miles with a population of 1,500,000. When the scheme for main drainage is completed it is asserted that it "will make Manchester one of the best drained and in every respect the most sanitary city in the kingdom."

Manchester Royal Infirmary: Post-Graduate Demonstrations.

In order to suit the convenience of practitioners it has been decided to alter the day on which medical demonstrations are given from Monday to Tuesday. The surgical demonstrations will be held as heretofore on Friday. The demonstrations will accordingly be given at 4.30 o'clock every Tuesday and Friday afternoon throughout the year, with the exception of Whitsun week and the months of April, August, and September.

Verdict of "Self-murder."

The Manchester coroner held an inquest on Jan. 23rd into the death of a married woman of Bolton from lead-poisoning caused by a drug she had taken. The grave crime of taking drugs in certain circumstances, said the coroner, was very prevalent among women. If a woman deliberately made up her mind to commit that crime, and took the drug in sufficient quantities to achieve her object, she might cause her own death. At first the jury wished to return a verdict of "Accidental death" on the ground that the woman had not intended to take her own life, but the coroner pointed out that the verdict was hardly in accordance with the evidence, for the woman knew what the risk was when she took the drug, and was warned when she bought the drug. Eventually a verdict of "Self-murder" was returned.

Athletics from a Medical Viewpoint.

Dr. A. Abrahams, in lecturing on this subject in Manchester on Jan. 24th, by means of a series of instantaneous photographs taken at critical phases of the movements of high jumpers, sprinters at the start, in their progress, and at the tape, hurdle jumpers, lawn tennis players, cricketers, and footballers, showed how such photographic records might be useful in exhibiting excellences or defects in style. A committee had been appointed to collect information and to inquire into the question of athletics with a view to putting games on a scientific basis, to ascertain the best methods of training. He had not been able to convince himself that smoking made any difference, perhaps because the athlete was always a very moderate smoker. He favoured those forms of exercise which had a high psychological as well as a physical value—tennis, golf, and the like. He did not think much of the "constitutional"—of walking—nor yet of swimming, because its physiological value was low and the person was moving in an abnormal medium, and perspiration was ineffective. Rowing was really a very severe form of exercise, partly because of the peculiarities of the breathing movements of the chest.

Jewish Hospital: A King Edward Ward.

In the annual report of the Jewish Hospital, Cheetham, it is stated that the King has honoured the hospital by permitting a ward "to be named to the memory of His Majesty King Edward." During the year 693 cases were treated in the hospital and 6816 in the out-patients' department. The income fell short of the expenditure by £426. Mr. Adolph Ahrens gave a donation of £1000, while £250 each were given by Mr. Mark Shaffer and Messrs. John Levy, J. N. Levy, Harry Levy, and C. L. Levy.

Vaccination Exemptions and Officials' Fees.

In the Altrincham, Wilmslow, and adjacent districts the increasing number of vaccination exemptions has greatly reduced the emoluments of the vaccination officers. In view of this fact the Bucklow board of guardians on Jan. 23rd decided to pay each officer 9*d.* for each exemption granted since April last year. The first exemption was granted only four years ago.

Important Cases under the Workmen's Compensation Act.

The point as to whether a miner with only one eye can work satisfactorily at the "coal face" was raised in the Salford county court before Judge Stanger on Jan. 16th. A miner claimed compensation from his employers in respect of an accident which he met with in one of his mines in December, 1908. While working at the "coal face" he was struck by a piece of ironstone on the right eye. Compensation was paid at the rate of 15*s.* 7*d.* per week until April, 1910. Other and lighter work was found for him for which he was paid 3*s.* 7*d.* per day with 6*s.* 7*d* per week partial compensation until August, 1911, when his employers considered him fit to go back to his work as miner. The question raised was whether a man who had practically lost the sight of one eye was fit to work at the "coal face," or only able to do the easier work which a day wageman has to do. It was contended that as the plaintiff was 52 years of age, and had lost an eye at that age, after 30 years in the mine, it was practically impossible for him to adapt himself to the altered conditions, having acquired his skill with the full use of his sight. Evidence was given for the defence that the injured organ had still a certain amount of capacity. The judge found that the man was not fit to work in the mine, but only on the surface, and awarded compensation at the rate of 6*s.* per week.

Another unusual case came before Judge Mellor on Jan. 25th. The applicant was married to her late husband in March, 1910, and he was killed while working as a carter for the defendant in June of last year. The widow had signed a paper expressing her willingness to accept £170 in full settlement. If she was wholly dependent she would be entitled to a full three years' wages amounting to £232. Before marriage she had earned 15*s.* per week; after marriage she continued to work and was still doing so. The registrar refused to sanction the settlement on the ground that the amount was not adequate. Ultimately a judgment for £192 was pronounced, as the widow was not wholly dependent on the wages of her late husband.

Large Bequests for Hospitals and Charities.

Miss Helen Swindells, of Elmstead, Birkdale (formerly of Bowdon), has left bequests, all free of duty, which include the following:—University of Manchester, to be applied by the Council of the University in aid of the Cancer Research and Pathological Department of the said University, £5000; Manchester Royal Infirmary, £4000; Manchester Hospital for Consumption, Hardman-street, and St. Mary's Hospital, Manchester, each £3000; Devonshire Hospital and Buxton Bath Charity, Northern Counties Hospital for Incurables, Manchester Children's Hospital, Pendlebury, Boys' and Girls' Refuges, Strangeways, Charter-street Ragged Schools, Street Children's Mission, Wood-street, and Crippled Children's Help Society, Cross-street, each £2000; Southport and Birkdale Nursing Society, £1000; and the sum of £5000 to form a fund for distressed ladies.

Cost of Lunatics in Lancashire.

At the Ashton board of guardians there was a call from the county council for £18 369. This is largely due to the increased cost of lunatics.

Jan. 30th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Hospital Sunday in Bristol.

THE collections for the Lord Mayor's Hospital Sunday Fund were taken in Bristol on Jan. 28th. The statement issued showed that the four principal institutions—the Royal Infirmary, the General Hospital, the Children's Hospital, and the Eye Hospital—had been responsible for the treatment of over 110,000 persons during 1910, their total ordinary income amounting to £7000 less than their ordinary expenditure. During the years of its existence this fund has amounted to over £23,000. The result of this year's collections is, of course, not yet known, so that it is impossible to say whether the total will be influenced by the Insurance Act. The Lord Mayor, Mr. F. W. Wills, speaking at the Colston Hall on the Sunday afternoon, pointed out that the illness for which treatment was provided by the Act was of a different type from that for which the hospitals were responsible, and that it was therefore as necessary as ever to subscribe liberally to their support. It was also pointed out from at least one pulpit in the city that the Act does not come into operation for six months, and that it is therefore incumbent on the citizens to provide for the upkeep of their hospitals during that period on the same scale as heretofore. There is unfortunately reason to believe that the subscription lists are already suffering as a result of the Act; whether this falling-off is temporary or permanent remains to be seen, and it is not yet possible to ascertain the effect of the Act on the contributions of workpeople, which form a large proportion of the regular income of the Bristol hospitals. At the General Hospital and at the Royal Infirmary the extension schemes, which are being pushed forward, show no signs of interruption, the committees no doubt realising that the public will need hospitals in the future as in the past, and that money will have to be found for their support, whether voluntarily or through Government channels.

Bristol Eye Hospital.

The 101st annual meeting of the Bristol Eye Hospital was held last week, the Lord Mayor being in the chair. The annual report stated that the increased accommodation provided by the centenary collections had been fully utilised; there had been 578 in-patients and 8258 out-patients, an increase of 131 and 1257 respectively over the preceding year. There was a deficit of £47 on the year, which would have been much greater had it not been for large anonymous donations given in response to an urgent appeal made through the press towards the end of the year. An additional £500 yearly in subscriptions is absolutely necessary. The Lord Mayor said that he had been surprised to find from the report how large a number of the patients came from outlying towns and villages, and he had felt this to be so important that he had addressed a special appeal for help through the Sunday Fund to the clergy of the various places sending patients to the hospital. Mr. F. Richardson Cross said, in reference to the Insurance Act, that its probable result would be to increase, and not to relieve, the work of the hospital. He also stated that no less than 932 of the patients seen at the

hospital during 1911 came from the school medical officers, although the education committee made no contribution whatever to the funds of the institution. As most of these are refraction cases a considerable strain is added to the already arduous work of the staff.

Lectures to Voluntary Health Visitors.

The first of a series of elementary lectures for voluntary health visitors and others, arranged jointly by the Mothers' School, the Civic League, and the Bristol Women's Local Government Association, was given last week at the University of Bristol by Dr. Annie Cornall.

The Residence of a District Medical Officer.

There has recently been some discussion by the Plymouth board of guardians in reference to the residence of one of its district medical officers. The gentleman in question does not reside in his district, but has a branch surgery there in telephonic communication with his house. The Local Government Board was prepared to sanction the appointment for three years. After several guardians had spoken highly of the medical officer's kindness to the poor, a resolution that he should be appointed for three years was defeated by four votes. It was then proposed that the appointment should be advertised, but eventually an amendment was carried to the effect that the medical officer should be given another opportunity to comply with the guardians' requirement that he should reside in his district.

Boric Acid in Sausages.

At the Exeter police court on Jan. 19th a local tradesman was summoned for selling sausages containing boric acid. Evidence showed that 1 lb. of sausages contained 52·5 grains of boric acid. The bench fined the defendant £2 and costs.

Proposed School Clinic at Plymouth.

The clinics subcommittee of the Plymouth Education Committee has recommended that the Board of Education be asked to give its approval to a scheme for providing a clinic for the children of parents who cannot afford to pay for a private medical man or who cannot obtain treatment at the various medical institutions in the town. The subcommittee recommends that the conditions treated by the school medical officer should be extractions of teeth, defects of ear (suppurative), skin diseases (including ringworm, scabies, and impetigo contagiosa), and pediculosis of the scalp and body. The subcommittee adds that it is impossible to state with any degree of certainty the number of children who will require treatment, and recommends that the school medical officer should have his salary increased by £50 per annum for the extra work he will be called upon to perform, and that the sum of £100 should be the limit of this expenditure for the financial year.

The Teignmouth (Devon) Hospital.

At the annual meeting of the subscribers of the Teignmouth Hospital held on Jan. 24th it was stated that the charity had been without a house surgeon for some six months, and that the duties had been performed by the honorary medical staff. Some discussion took place upon the question of obtaining a house surgeon, and it was thought that the salary of £80 per annum, which was offered, was not sufficient. Eventually it was decided that the medical staff should report upon the subject to the committee.

The South Devon and East Cornwall Hospital, Plymouth.

The treasurer of the South Devon and East Cornwall Hospital states that during 1911 the institution received £838 from the Hospital Sunday Fund and £581 from the Hospital Saturday collections.

Death of Brigade-Surgeon-Lieut.-Colonel T. G. Skardon.

Brigade-Surgeon Thomas Gray Skardon died at his residence, "Simla," Paignton, Devon, on Jan. 24th, aged 75 years. He received his medical education at St. Thomas's Hospital, London, and took the M.R.C.S. qualification in 1859. A year later he entered the Indian Medical Service, serving with the Bengal Army. After 25 years' service in India he retired and took up his residence at Paignton. He soon became very popular there, and took great interest in all local matters. He was a staunch Churchman, and with some other residents was instrumental in the building of Christ Church, Paignton. He was greatly interested in missionary work. The funeral took place at Maker, near Plymouth.

Death of Dr. William Dashwood Kingdon.

Dr. W. Dashwood Kingdon died on Jan. 20th at his residence, Heavitree House, Exeter, in his ninety-ninth year. The deceased, who received his medical education at Edinburgh University, graduated M.D. in 1837, and in the same year was admitted L.R.C.S. of Edinburgh. Dr. Kingdon was well known and highly respected at Exeter, and was at one time physician to the Exeter Dispensary and resident medical superintendent of St. Thomas's Lunatic Hospital, Exeter. He had retired from active work for some years. He took a great interest in Freemasonry, and was stated to be the oldest "Mason" in the world. The funeral took place at the Higher Cemetery, Exeter, on Jan. 25th.

Jan. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Act.

CONSIDERABLE surprise is felt and expressed that the Insurance Commissioners, in their letter of Jan. 24th, addressed to the British Medical Association, asking them to appoint 20 members, selected from England, Scotland, and Wales, to attend a conference on Feb. 2nd, have totally ignored Ireland. Ireland has no medical benefits, it is true; but, on the other hand, workmen who come over to Ireland from other parts of the United Kingdom, having previously registered there, will be entitled to receive medical benefits while in Ireland, and in that country sanatorium and maternity benefits exist under the Act. All sorts of medical certificates, moreover, will be required, so it is not clear why Irish practitioners are not asked to join in this preliminary conference. At a meeting of the Ulster Branch of the British Medical Association held in Belfast on Jan. 25th a discussion took place in reference to the appointment of an organising committee for Ulster, and it was finally decided to ask the Council of the Ulster Branch to select the names, taking care that the various towns and districts were fully represented. The Presbyterian Church of Ireland and the Methodist Church are taking action to form approved societies under the Act, and it is also stated the Church of Ireland will act in the same direction.

Irish Milk-supply.

The Vice-Regal Commission on Irish Milk-supply has continued its sittings. Last week Mr. E. Kennedy, of Straffan Station Stud, expressed the opinion that tuberculous disease was increasing steadily among cattle. Tainted milk was mixed in the same creamery vat with sound milk, and all the milk became tainted. He believed that an increased percentage of affected cattle was caused by feeding calves on separated milk and by the bad conditions in which the cattle were housed. A regular and recognised trade was being done at fairs in these tuberculous cattle, or "spiners." Cattle in an advanced state were sold as "sausage meat." Miss Martha Lough, of Killeshandra, on the other hand, said she was a strong believer in separated milk, and thought it a most useful food for calves and people. Mr. J. H. M'Grane, dairy inspector, South Dublin district council, was not aware of a single case in his district of infectious disease being traced to a dairy, or having been disseminated by the milk of the district. Mr. J. D. Richardson, veterinary inspector, North and South Dublin rural district councils, said that the number of diseased animals in his district had considerably decreased during the past three years. In the city the owner of an animal that was destroyed was compensated, but in rural districts no compensation was given to the owner. He was in favour of the licensing of dairy proprietors. Dr. John Lumsden, physician to Mercer's Hospital and chief medical officer to Guinness's brewery, said that since 1908 he had had under observation 120 sick babies that were supplied with milk from the depôt of the Women's Health Association at Sitric-road, and among the 120 only 5 deaths had occurred, the ratio being 41 per 1000, as compared with 145 in the city. He had never seen any harm result from the use of pasteurised milk. As a clinical observer he had seen no harm result from the use of boiled milk.

Reception at the Royal College of Surgeons.

The President of the Royal College of Surgeons and Mrs. Robert Woods gave a reception to a large number of visitors

last Saturday evening at the College, to have the honour of meeting their Excellencies the Lord Lieutenant and the Countess of Aberdeen. Uniforms, decorations, and academic robes were worn. Objects of scientific interest were exhibited by Professor J. A. Scott and Professor Arthur H. White, and adulterants of food were shown by Sir Charles Cameron. The reception was attended by a large number of medical men, as well as by representatives of various other professions. The College has rarely, if ever before, been thrown open for an evening party.

Research Defence Society: Dublin Branch.

The annual meeting of this branch was held on Jan. 25th, Sir Charles Ball presiding. The annual report stated that the number of members was over 500. A ladies' committee had been formed, which had undertaken to arrange drawing-room meetings at which information should be given as to the objects of the society. A lecture was delivered by Dr. Leonard Hill, professor of physiology in the London Hospital Medical College, on "Submarine Diving Made Safe and Possible through Experiments on Animals." He dealt with what has so far been accomplished through the medium of scientific research, by means of experiments on animals, to make the operation of compressed air work safe for those engaged in it. He mentioned that formerly work, such as the building of harbours, piers, &c., was attended with great danger to life and health, but scientific investigation had done much to show that those evils could be avoided, new and improved methods having been discovered as a result of experiments which had been made upon such animals as frogs, rabbits, and cats, and the work could now be carried out with safety. One of the most important discoveries had been made by Dr. John S. Haldane, a distinguished member of the Research Society, who proved that in deep-sea diving illness among divers was caused, not by increased pressure, but by insufficient air. By using additional pumps increased pressure was forced down to the diver, who was enabled to overcome carbonic acid poisoning.

The Belfast Medical Students' Association.

At the annual public meeting of this association, held on Jan. 27th in the Students' Union of the Queen's University of Belfast, the inaugural address was delivered by Dr. W. W. D. Thomson, the new President, on the Struggle for Truth in Medical Science throughout the Ages. Sir Thomas Myles, of Dublin, followed with an address on the Medical Student as I Know Him.

The Belfast Hospital for Sick Children.

At the thirty-ninth annual meeting of this institution held on Jan. 25th the medical and surgical report, submitted by Dr. John McCaw, secretary of the medical staff, showed that during the past year 672 patients had been treated in the wards (361 medical and 311 surgical), while in the out-patient departments 3936 new cases were registered. Thirty-one senior students are attending the clinics, the local Queen's University having wisely made diseases of children a compulsory subject for those seeking its medical degrees, as well as requiring candidates to produce a certificate of having attended a special practical course in hospital on diseases of children. Fears were expressed both in the report and by subsequent speakers as to the serious effect of the Insurance Act on subscribers to the hospital, especially as children paid no insurance and received no benefits under that measure.

Londonderry Nursing Society.

At the annual meeting of this society held in Londonderry on Jan. 23rd, the Duchess of Abercorn presiding, a very satisfactory report was read. Dr. G. B. McCaul mentioned that during the year 1339 new cases had been attended to by the nurses. Lady Hermione Blackwood also gave an address at the meeting.

Appeal on Behalf of Miss Daly.

An appeal signed by Dr. M. Cagney, of South Mall, Cork, and Mr. Philip G. Lee, of St. Patrick's Hill, Cork (either of whom will receive subscriptions), has been issued to the Cork medical profession on behalf of Miss Daly, who through the death of her brother, the late Dr. Pierce J. Daly, of Cork, is now left absolutely devoid of means, and in shattered health in consequence of long years of devoted nursing. Subscriptions to the extent of £395 have so far been made, but a more liberal and substantial response will be required in order to enable her to avoid having to enter a public charitable institution.

Jan. 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Sale of Quinine in Annam.

THE Chief Resident in Annam has taken the following measures for the sale of quinine at a low price, its free distribution being for the time suspended. The sulphate in compressed tablets will be used. The price for each province will be settled by the Resident at a round sum without any profit for the administration. A central depôt will be established at the principal settlement, under the control of the chief surgeon, who will indicate the necessary depôts to be established by decree of the Resident, use being made of the wine-shops and the rural post-offices, preferably of those situated in the regions most affected by malaria. The local sanitary officers will give instruction as to the details of application, and will take advantage of their tours of duty to inform the natives of these plans, the dose, method of use, and price of the drug. Posters containing like information will also be affixed on the doors of the secondary depôts.

Special Rights of Way for Paris Medical Men.

M. Massard, a municipal councillor, has laid before the council a measure the adoption of which would render great service to Paris medical men. It calls on the Prefecture of Police to establish a special right of way for medical men, conferring on them the right of priority in public vehicles, to be obtained by extra payments, and of having first access to the Metropolitain. This measure is all the more justifiable inasmuch as medical men are not usually too well off, and in the matter of transport they make use for the most part of the public means of conveyance, while their engagements are always a matter of urgency. The badges issued to journalists are useful, but a special badge would be quite fitting and certainly as useful for medical men, who should not be hindered in the discharge of their duty.

Preserving the Transparency of the Human Cornea.

The transparency of the cornea of the eye is of great delicacy. Very quickly after the removal of the eye, or after death, the eye becomes glazed and its epithelium desquamates. M. Magitot recently reported to the Academy of Sciences his success in preserving for 15 days after removal the optical qualities of a human eye from which a graft was to be made. A glaucomatous eye had to be removed on account of intolerable pain. Sight in this eye had been definitely lost for months, and it was so tense that the cornea was insensitive and even opalescent. The entire eye, immediately on enucleation, was washed in Locke's solution, and immersed with all aseptic precautions in a flask containing blood serum from another person. It was then put in cold storage at 5 to 6° C. At the end of some hours, the internal pressure of the eye having fallen, the cornea had regained its transparency. This eye was kept for eight days. Then a rectangular piece, half the thickness of the cornea, was taken carefully and inserted into a cavity of the same dimensions made in the cornea of another patient, who some years before had had some quicklime in his right eye, in consequence of which the cornea had become opaque almost throughout. The graft from this tissue, preserved for eight days, was inserted without sutures to the right side of the pupil, thus forming a little window about 5 by 4 mm. At the end of 38 hours the transplanted tissue had perfectly adhered. For seven months the foreign tissue has now been tolerated, has retained its transparency, and affords the patient sufficient power of vision to get about with. To obtain this result the author recommends that an appropriate medium be chosen, consisting of the hæmolysed serum of an individual of the same species. The hæmolysis should be brought about by purely physical means—e.g., rapid fall of temperature by collecting the hot blood in a vessel chilled by ice. A low, but not too low, temperature is necessary, the most suitable being between 4° and 7° C., and it should be constant.

Radiography of the Viscera.

On Jan. 25th the Société de l'Internat des Hôpitaux held its first annual session under the presidency of Dr. Monprofit, the subject under consideration being radiography of the viscera. Radiography is now widely used in the diagnosis of visceral pathology, and even if it cannot furnish

a certain diagnosis, at least it helps in establishing one. All the mistakes made in radiography must be due to errors of interpretation. M. Aubourg showed on the screen M. Delherm's pictures of the lungs, demonstrating the radiographic signs by which the practitioner can diagnose tuberculosis, pulmonary congestions, abscess of the lung, cysts, with displacement of the vital organs, and diaphragmatic pleurisies. He subsequently demonstrated the stomach and intestine in like manner. M. Lebon showed pictures of the heart and the aorta, and M. Beaujard of the kidney and the bladder.

Death of Professor Albarran.

French science has been plunged into mourning by the death of Professor Albarran, who died after an illness lasting almost three years. Although born in Cuba, M. Albarran had lived nearly all his life in France. From the outset of his career he distinguished himself by his diligence, his intelligence, his accuracy, and the originality of his researches. In his promotion to the internship he came out first in the list, and received the gold medal. As a pupil of Professor Guyon he naturally followed in the same course, and succeeded him in his chair. He has done much work on the bacteriology of the urinary passages, on tumours of the bladder, prostatectomy, and catheterism of the ureter. He attained the goal of his ambition early, and has left behind him an honourable name.

Jan. 29th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Ontario Vital Statistics, 1910.

THE Registrar-General's Department, Ontario, in the Blue-book shortly to be issued, will report for the year 1910 that there were 55,871 births, 24,036 marriages, and 33,539 deaths in the province during that year, or 24·9, 10·7, and 14 per 1000 of the estimated population. In the cities, for births, marriages, and deaths there is a ratio of 32·2, 20·2, and 21·1 per 1000, while in towns under 5000 population and the country districts the ratio is 21·6, 10·4, and 14·7 respectively. Of the total number of deaths—33,539—there were 706 from typhoid fever; 2287 from tuberculosis in all forms, which was 103 less than in 1909; cancer, 1077; diabetes, 222; anæmia, 327; meningitis, 355; apoplexy, 923; organic heart disease, 2240; broncho-pneumonia, 464; pneumonia, 1458. Diarrhœa was fatal to 1374 infants under 2 years of age, while 2455 died when under 4 months of age. In 284 cases women lost their lives in childbirth. Ninety-one persons took their lives by various methods, 26·3 per cent. by hanging; 266 were drowned; 209 killed by motor-cars; and 17 homicides. Old age was the cause of death in 3429 persons. There were 2207 stillbirths. In infants 6649 died under one year of age, 917 one year old, 424 two years old, 321 three years old, and 247 four years old. The male children born numbered 28,664 and female 27,207. There were 370 pairs of twins, 364 boys and 376 girls; and triplets in five cases, 9 boys and 6 girls. Of the men who married about one-third did so between the ages of 20 and 24, and nearly one-half the women between those ages. Out of a total of 7351 Roman Catholics married, 1509 married out of their denomination, and this in spite of the *ne temere* decree, over which there has been so much discussion in Canada the last two years. Of the grooms, 665 married non-Catholic brides, while 844 professed Catholic girls married non-Catholic grooms. The larger number of these mixed marriages was between Catholics and Anglicans.

The Division of Professional Fees in Toronto.

Early in the year 1908 some interesting letters appeared in THE LANCET on the question of the division of the operation fee between the operator and the general practitioner, and a leading article also dealt with the matter.[1] Recently a motion at a meeting of the Academy of Medicine, Toronto, set out that the *secret* division of a fee or fees with any person or persons who may be instrumental in influencing a patient or patients to apply for operative care or professional advice is unworthy of any member of the medical profession. The motion further asserted that it would be the duty of the council of the Academy to investigate charges under this heading against members, and on proof of guilt either to permit the resignation of the offender or to expel him from the Academy. The questionable practice known as dichotomy has infected the medical life of the United States. The Canadian profession, however, take their professional ethics more from Great Britain. After an extended discussion the Academy has referred the matter to a special committee, which is invited to submit an exhaustive report on a basis of future action.

[1] THE LANCET, vol. i., 1908, pp. 596, 676, 813, 889, 1032, 1108, 1353.

Reorganisation of Montreal Board of Health.

A deputation of Montreal physicians recently waited on the Board of Control of that city asking that the civic Health Department be reorganised. From the following list of requirements it will be seen that little short of a revolution was asked for. The deputation suggested that the Health Department should control all street cleaning and sewerage; that all employees connected with the city's health should be under the control of the health officer; that there be a medical library for the use of health inspectors, and that lectures be delivered to them; that all employees of the department of health be made to pass examinations and should receive certificates; that nurses be employed to instruct young mothers in the care of infants; that the medical inspectors be given good salaries and not permitted to engage in private practice; that all cases of contagious diseases in the city be promptly reported to the Health Department by practitioners and others; that the Health Department send to the local medical profession monthly reports of the health of the city; that chemical and other departments be created and attached to the Health Department; that fines and penalties on all who disobey the health laws be made more severe; that refrigerator cars be used by railways for the conveyance of milk; that new incinerators be constructed; that steps be taken to establish tuberculosis hospitals in different parts of the city; and that vaccination be made absolutely compulsory.

Public Health Organisation in Ontario.

Dr. J. W. S. McCullough, chief medical officer for the Ontario Government, who is now in the United States investigating the most recent advances in public health matters in that country, will, on his return to Toronto, and prior to the approaching session of the Ontario Legislature, recommend the abolition of the boards of health in the counties of the province, and the substitution therefor of health districts in charge of whole-time health officers. The province will be divided into seven or eight districts, each in charge of an experienced medical man, and instead of being appointed by local authorities these will be appointed by the Government and will be directly responsible to the chief medical health officer. There are at the present time about 800 boards of health in Ontario and as many local officers. The work in most cases is very perfunctorily performed as the remuneration is decidedly small, as a rule the amount paid being less than $50. It is not intended to interfere with the boards of health in the large cities, where competent health officers are engaged with suitable salaries.

Jan. 12th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The New Surgeon-General of the United States Public Health and Marine Hospital Service.

President Taft has appointed Dr. Rupert Blue, of South Carolina, surgeon-general of the United States Public Health and Marine Hospital Service, in succession to the late Dr. Walter Wyman. Dr. Blue graduated in medicine at the University of Maryland in 1892, and entered the Public Health and Marine Hospital Service in 1893. As already mentioned in this column, he did excellent work during the plague epidemic in San Francisco. When announcing the appointment President Taft gave notice that hereafter the term of service of the surgeon-general shall be limited to four years.

The Mott Library Transferred to New York Academy of Medicine.

Dr. Valentine Mott, a well-known New York surgeon who died in 1895, left instructions with his widow that his

valuable medical library and instruments should be housed and established at the Mott Memorial Library. In 1896 Mrs. Mott bought a house in Madison-avenue for the purpose. The library was dependent upon public contributions. The trustees, discovering that it was being conducted at a loss, in accordance with a provision in Mrs. Mott's will have decided that the house shall be sold and the proceeds divided among her heirs. The contents of the library and the instruments have been turned over to the New York Academy of Medicine.

The New York Post-Graduate Hospital.

A dinner to commemorate the opening of the new buildings and laboratories of the Post-Graduate Medical School and Hospital, New York, was held at Delmonico's on Jan. 10th. More than 200 members of the staff and their guests were present. Among the speakers were Dr. Samuel W. Lambert, Dean of the College of Physicians and Surgeons of Columbia University; Brigadier-General G. H. Torney, surgeon-general of the army; Dr. Abraham Jacobi, president of the American Medical Association; and Augustus E. Thomas, the playwright.

Fire at the Massachusetts State Leper Colony.

The administration building at the Massachusetts State Leper Colony on Penikese Island was burned down on Jan. 13th, causing a loss of £2000.

The New Buildings of Harvard Medical School.

The establishment of Harvard Medical School will consist of 16 institutions when the six buildings now under construction are completed—viz., the Harvard Memorial Cancer Hospital; the Infants' Hospital, known as the Thomas Morgan Rotch, jun., building; the Children's Hospital; the Peter Bent Brigham Hospital, which has a combined fund for building and endowment of £1,200,000; the State Psychopathic Hospital; and the Robert Brigham Hospital. A project is also afoot to erect a Harvard dormitory and medical union club-house, to be conducted on principles similar to those of the Harvard Union and Dormitories, but confined exclusively to medical and dental students.

A Medical School for the University of California.

At a recent meeting of the Board of Regents of the State of California plans were adopted for the amalgamation of the various departments of medical instruction under the supervision of the University of California. It was decided to secure the services of paid instructors for clinical instruction in place of the voluntary services of practising medical men. The principal chairs of medicine, surgery, and obstetrics will be held by professional instructors, who will devote their whole time to teaching or research work.

Jan. 20th.

Obituary.

SIR HENRY TRENTHAM BUTLIN, BART., F.R.C.S. ENG.,

LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND OF THE BRITISH MEDICAL ASSOCIATION; CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

ON Wednesday, Jan. 24th, Sir Henry Trentham Butlin died at his residence, 82, Harley-street, after an illness of some two months' duration.

Henry Trentham Butlin was the son of a Cornish clergyman, the Rev. W. W. Butlin, and was born in 1845 at Camborne in that county. He was privately educated until he went to St. Bartholomew's Hospital, where he entered as a student in 1864. Here he commenced his medical studies under favourable auspices, for St. Bartholomew's Hospital at that time had a strong honorary staff, while among the lecturers and teachers Sir James Paget was outstanding. To him Butlin particularly attached himself, and he always acknowledged his great indebtedness to him for the professional success that fell to his share. Butlin succeeded, if anyone ever did, entirely on his own merits; he owed nothing to outside influence, to court or social connexions, or indeed to anything but his own capacity and his high character. He was remarkable as a student by his industry and intelligence, and his career is an exemplification of what these qualities can accomplish when they pursue without faltering a clear and well-defined objective.

He qualified as M.R.C.S. Eng. in 1867 and as L.R.C.P. Lond. in 1868, and in the same year became house surgeon of his hospital. On the completion of this service he entered on country practice, but almost immediately found that his ambitions were centred upon a hospital career. He returned to London in 1870, and began at once to lay the foundations of the distinguished future that was to be his. In 1871 he took the Fellowship of the Royal College of Surgeons, and in the same year was appointed surgical registrar at the Great Ormond-street Hospital for Children, and assistant surgeon to the West London Hospital. He was also connected at one time with an orthopædic hospital as well as with the Metropolitan Free Hospital.

In 1872, the post of surgical registrar at St. Bartholomew's Hospital becoming open, he gladly seized the opportunity thus afforded him of fulfilling his devoted hope of a permanent association with his hospital. In 1873 he gained the coveted Jacksonian prize at the College of Surgeons for his essay on Ununited Fractures. In 1879 he was appointed Demonstrator of Surgery at St. Bartholomew's Hospital Medical School in succession to Professor Howard Marsh, now Master of Downing College, Cambridge, and in this post he soon made an indelible mark. Butlin showed himself at once to be an admirable clinical teacher, keen of observation and accurate in deduction. In 1881 he became assistant surgeon to the hospital and lecturer on surgery. He served as assistant surgeon until 1892, when he became full surgeon, which post he relinquished only in 1902, after 21 years' service on the staff, and was then appointed to the consulting staff. The columns of THE LANCET and *British Medical Journal* testify to the value of the work he did in the hospital during this lengthy period, and it is interesting to record that Butlin, whose clinical lectures were such fine and thoughtful deliveries, disapproved of formal lectures as a part of the compulsory medical curriculum and had designed himself to make proposals for abolishing them. In 1880 Butlin was appointed Erasmus Wilson Professor of Pathology at the Royal College of Surgeons of England, being the first to occupy that post after Sir Erasmus Wilson himself, and he gave the first indications of a direction which he was to follow throughout his career in the selection of a subject for his lectures—viz., the Relations of Sarcoma to Carcinoma. These lectures admirably reflected the practical lessons to be drawn from a clinical study of malignant disease, more especially with reference to the principles governing operative interference. They were republished in book form in 1882 with valuable additions to the tables of cases and additional matter on diagnosis and treatment. Their most striking feature was the care taken to have the data as satisfactory as possible, all the cases utilised being submitted to microscopical examination and the structure of the new growths in every instance being ascertained with precision. In 1887 he published "The Operative Surgery of Malignant Diseases," a book written not to establish any new position or to defend any novel procedure, but rather to formulate the results obtained up to date, showing the bad as well as the good side of operative interference, and containing a collection of statistics that should serve both to restrain and yet to encourage the operator. He laid great stress on the importance of removing widely all malignant tumours—a principle now generally admitted and acted on. Other papers bearing on this subject were articles on tumours in the *International Cyclopædia of Surgery*, on Malignant Diseases (Sarcoma and Carcinoma) of the Larynx, and on Tumours in the third edition of Holmes's "System of Surgery." In 1892 Butlin was appointed Hunterian professor of surgery and pathology at the Royal College of Surgeons, and in 1895 he became a member of council in the presidency of the late Mr. Christopher Heath, his official connexion with the College continuing unbroken from that time on. In 1909 he succeeded Sir Henry Morris in the presidential chair, an office that he relinquished only on Nov. 9th last on account of failing health. In 1893 the University of Durham conferred on him the honorary degree of D.C.L., an example followed by the University of Birmingham in 1910 with the honorary degree of LL.D.

In his Bradshaw Lecture in 1905 Butlin insisted, in the face of the almost unanimous opinion of pathologists, "that carcinoma is a parasitic disease, not in the limited sense in which the term appears to have been used of late as synonymous with infective, but in the larger and wider sense in which it used to be, and should always be, employed, to express the fact of one organism living at the

expense of another organism, each pursuing its otherwise separate and independent existence." Of his Hunterian Oration, delivered at the College of Surgeons on Feb. 14th, 1907, it would be hardly possible to speak in terms too high. It is questionable whether on any previous occasion so adequate a tribute to the memory of John Hunter has ever been paid from that chair. Butlin insisted on the fact that the true value and greatness of Hunter's work lay in his anticipating what still needs to be impressed on many, that the key to the prevention or treatment of disease must be sought and can be found only in the investigation of natural function. He powerfully assisted his audience to grasp the fact that this position entitled Hunter to take rank, not only with the most eminent members of his own calling, but with the small band of philosophers whose researches in various departments of learning have gained for the human race its power to guide and utilise the forces of nature. To add to the charm of this oration it was delivered perfectly clearly and without hesitation as a speech, the speaker being unaided even by notes. The delivery was a triumph of accurate thinking and good memory, and reminded those who heard the oration of some of the oratorical triumphs of Butlin's dead master, Sir James Paget.

During 1910–11 Sir Henry was President of the British Medical Association, and in this capacity he was entertained on June 17th, 1911, at what is believed to be the most largely and representatively attended dinner ever given by the profession to one particular medical man. Over 200 members of the profession were present, drawn, no doubt, by varying ties, which, however, in themselves bespoke the broad gauge character of the man and his activities. As the chairman, Dr. Lauriston Shaw, then pointed out, his affiliations, not only with the British Medical Association, but with the Royal College of Surgeons of England, with the University of London, St. Bartholomew's Hospital, the Pathological and the Laryngological Societies (both now merged in the Royal Society of Medicine, and of both of which he had occupied the presidential chairs), with the Society of Surgeons of Paris and that of Laryngologists of Berlin, all combined to bring together so large and so representative a body of men to do him honour, the relationship of a trusted consulting surgeon to a large number of general practitioners helping to swell the number of those present. His connexion with the British Medical Association was a very close one; he was a member of the Council of that body for many years, of its Journal and Finance Committee, its treasurer, and, finally, in 1910–11, in which year the Association held its annual meeting in London, its President. In all these varying capacities and activities Sir Henry was successful in the most practical way—that is, he left every institution that he served distinctly and appreciably the better for his service. He was unflagging in his zeal, tactful and adaptable, yet without sacrificing his own convictions, even in those matters on which opinions ran contrary, while his gifts as a speaker materially aided every cause he supported. In all things he was guided by ardour for the highest welfare of the profession. There can be little doubt that the arduous exactions of the manifold responsibilities he took upon himself helped to undermine a physique never too strong.

Among Butlin's literary works, other than those already referred to, may be mentioned a paper on the Nature of Fur on the Tongue, published in the Proceedings of the Royal Society for 1879; a Report on Certain Tumours removed in St. Bartholomew's Hospital, with Remarks on the Growth of Fatty Tumours (St. Bartholomew's Hospital Reports, 1873–74); on Minute Anatomy of Two Breasts, the Areolæ of which had had Long-standing Eczema (Medico-Chirurgical Society's Transactions, 1876); and Reports on Cancer for the Collective Investigations (*British Medical Journal*, 1887) His book on "Diseases of the Tongue," published in 1885, was a model of concise writing, logical reasoning, and lucid exposition, particularly in the part relating to cancer, the subject to which he devoted so much of his attention throughout his professional career.

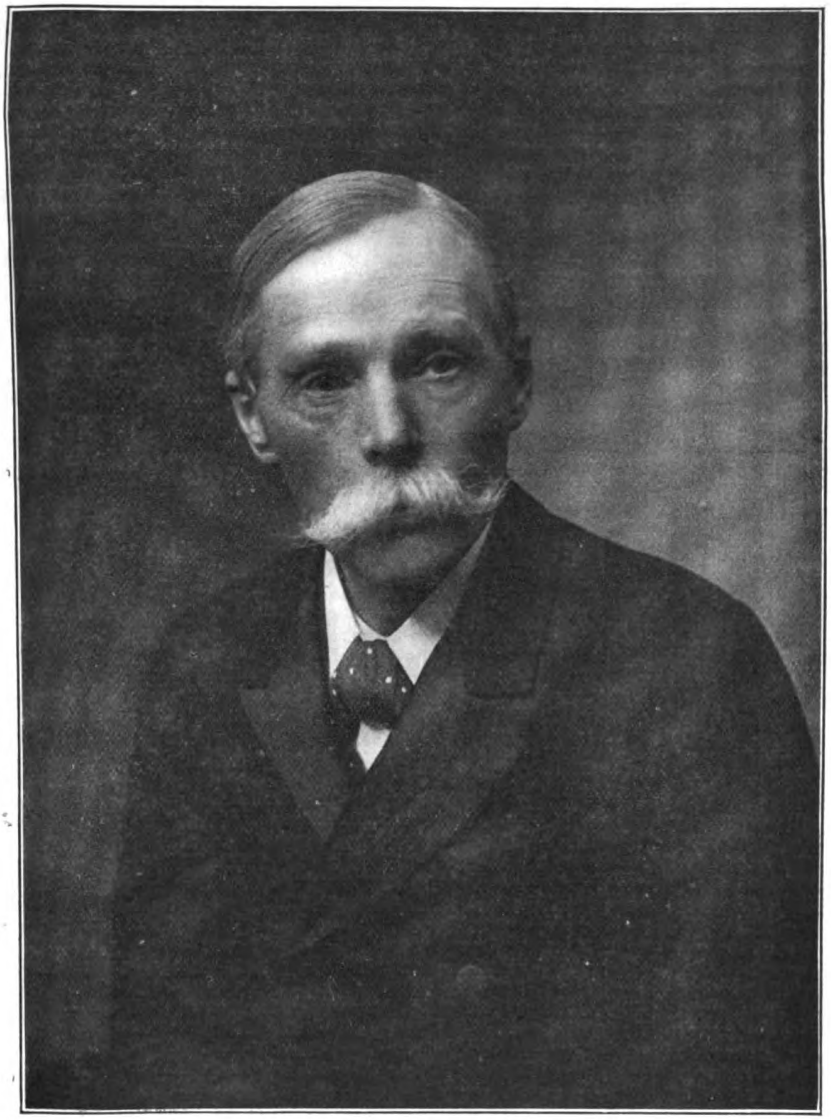
Finally must be mentioned the two lectures on Unicellula Cancri, the Parasite of Cancer, delivered by him before the Royal College of Surgeons last November, in which he expands the idea referred to in his Bradshaw lecture of 1905—viz, that the cancer cell is an independent organism, like many a protozoon; that it lives a life which is wholly independent and proper to itself; and that it lives in the body of the animal affected with the cancer, deriving its nourishment from its host and yet doing nothing to repay the host for the sustenance supplied to it. He concludes that the cancer cell is a veritable parasite formed from the very tissues of its host, remaining in appearance like the cells in which it first appears; he regards it as an independent parasitic animal which he names the unicellula cancri, and is inclined to place among the protozoa. Even if we are not able to agree with this view, the high gifts of its author and his lifetime of experience devoted to the study of the subject must surely make us suspend judgment until more conclusive findings shall either endorse or disprove it.

Sir Henry Butlin, who was made a baronet last year among the Coronation honours, married Miss Annie Balderson, daughter of Mr. Henry Balderson, of Hemel Hempstead, who survives him, and to whose devoted counsel and assistance he paid a touching tribute in his remarks at the dinner above referred to. He leaves also a son, now Sir Henry Guy Trentham Butlin, who was educated at Eton and is at present at Trinity College, Cambridge, and two daughters, one of whom is married to Mr. Percy Furnivall, F.R.C.S.

The following brief but intimate sketch of Sir Henry Butlin's work and character is from the pen of his pupil, friend, and colleague, Mr. C. B. Lockwood:—

How memories linger! Years have passed, but yet one remembers a slight, almost boyish form leaning over the cases in the dim light of the old museum, and quietly, patiently, conscientiously teaching a small attentive class, usually consisting of pupils who lived in his house, for then it was more the custom than it is now for the younger men to take resident pupils. The spacious, thoughtful brow, which looked so white in contrast with the dark and somewhat long hair; the steadfast, clear eye; the firm mouth; the well-poised head—all denoted the gifted being. Then, later, kindly advice, tendered in kindly way and with the pleasantest voice and tone, were added memories. Afterwards writing his registrar's notes in the same quiet, thorough way, and at surgical consultations giving his opinion simply and clearly in a few well-chosen words. Finally, a colleague and sincere friend. It is hard to think that ere those early days he had been in country practice. Those who are not affluent and who marry early must needs keep the wolf from the door. He seldom talked about those country days. To one such as him the daily round the trivial task of a country doctor's life must have left much to be desired. He used to tell how once an unfortunate farmer caught his arm in a machine, and amputation had to be done. Help was scarce, so one of the farmer's men held the limb. He proved efficient, and afterwards gave expression to the anxiety he had gone through, saying: "I thought it all up with master till I saw them little pinchers." Henceforth hæmostatic forceps were often called "them little pinchers." It is easy to guess that at this time he was conscious of possessing superior gifts, and felt impelled to seek a wider sphere for the display of his talents. No small courage was needed. But lack of courage was never one of his attributes. He had the bravest heart. Convinced that he was right he went dauntlessly on, although his keen, intuitive mind had told him all the dangers and difficulties to be faced. So it is not surprising that he put it to the touch and did not fear his fate; came to town and began a toilsome ascent to fame and honour.

His familiar friends know how hard it was at first for him and his true and wise helpmate. Sensitive in a high degree, all his courage was needed to carry him through the early trials of surgery. He said that at first when he had to perform operations at the West London Hospital the feeling of anxiety was almost overwhelming. And yet he became a calm and intrepid operator, one who patiently, quietly, and steadily set to work to do his utmost to extirpate the most widespread malignant growths. In spite of weariness and physical exhaustion he went steadily on. Never of robust physique, and not blessed with that abundance of health and energy which some enjoy, few knew what those efforts were, but to those who knew they were heroic, and gave rise to feelings of the deepest admiration and respect. Those long and exhausting afternoons of toil in hot operating theatres, and in such a fatiguing atmosphere, were bound to tell upon his frail physique. But of his troubles he used to joke and make light: "One day, my dear boy, you think there is a



SIR HENRY TRENTHAM BUTLIN, BART., D.C.L., LL.D., F.R.C.S.,
LATE PRESIDENT OF ROYAL COLLEGE OF SURGEONS OF ENGLAND; CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

malignant tumour in your inside. Next day you wake up and find it gone, and say to yourself it was that horrid gout again." So conscientious in the performance of duty, and so loyal to his hospital and school, he gave up the burdensome task none too soon. Without being humorous himself, yet he had the keenest appreciation and enjoyment of the quaint or humorous, and this trait added much to his happiness and to the happiness of others. But he had also other and soberer characteristics. Not a hero-worshipper, yet he had a hero, and he was Paget. Without a doubt Paget was his model orator—one whose style could hardly be excelled, especially that of his clinical lectures. But the oratory, the genius, the fame of Paget, were not the things of which he spoke so earnestly and feelingly. "Sir James Paget was one of the best men I ever knew; he was a truly good man"; and this was no chance utterance, but often repeated, and a clue to his own ideals of conduct.

It can be truly said of Butlin that he, too, was a good man, blameless in life and conduct. He did not hastily admit anyone into the circle of his intimate friends, but was never tired of entertaining those of whom he was fond. Indeed, he lavished kindness and hospitality, and those who met so often at his table usually found that juniors, whose opportunities of social enjoyment were few and far between, had not been forgotten. Indeed, he had very strong opinions on the duties of hospitality, and considered that we in London were wanting in this respect, and spoke warmly of the lavish hospitality of the provinces during the annual meetings of the British Medical Association. Always generous, during his recent presidency of the Association he expended a sum larger than most dreamt of in a banquet arranged purposely for the entertainment of the provincial visitors. It was characteristic of him to give a large contribution to the Faculty of Medicine of London University when he became its Dean, and he always evinced the keenest pleasure when his friends assisted in the good works in which he was interested. A delightful friend, he revealed his constant thoughts in moments of quiet companionship. It was then that one learned the affection he felt for his aged parents; his gratitude for all the help given by his wife; the pleasure that he took in regaining the broad acres which had long before belonged to his family; the pleasant days spent in looking after them; and the deep interest aroused in him by the education of his son. Begun with a memory, this note ends with a memory; the memory of a brave, indomitable man, a loyal colleague, a steadfast friend. Surely he will not "with sparkless ashes fill an unlamented urn."

Funeral services, which were largely attended by the medical profession, personal friends, and representatives of scientific societies and charitable institutions, were held at St. Bartholomew's the Less and St. Andrew's, Wells-street.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Franz von Winckel, formerly professor of midwifery and gynæcology in the University of Munich, at the age of 74. He was the son of Dr. Ludwig Winckel, who in his day was well known in connexion with the practice of Cæsarean section. After graduating in medicine in Berlin he was assistant to Professor Martin, senior, in the Charité midwifery wards, and when only 27 years old was appointed to the chair of obstetrics and forensic medicine in the University of Rostock. In 1872 he went to Dresden, where he was director of the famous midwives' school, and in 1883 was appointed to the chair of midwifery and gynæcology in Munich, from which he retired only four years ago. His works include "Manuals of Midwifery and Gynæcology" and articles in Billroth's "Handbuch der Frauenkrankheiten." He also published several works dealing with the duties of midwives. He was one of the founders of the German Gynæcological and Obstetrical Society, and edited the society's valuable clinical reports.—Dr. Edmund Biernacki, professor of pathology in the University of Lemberg.—Dr. P. Giura, *privat-docent* of stomatology in the Genoa Medical School.—Dr. A. Serafini, professor of experimental hygiene in the University of Padua.—Dr. O. F. Wadsworth, formerly professor of ophthalmology in Harvard University.—Dr. J. T. Davidson, professor of ophthalmology and otology in the Medical College of Virginia, Richmond.—Dr. S. B. Bond, formerly adjunct professor of genito-urinary diseases in the University of Maryland, Baltimore.—Dr. Rhett Goode, professor of anatomy and surgery in the Medical College of Alabama, Mobile.—Dr. P. D. Hughes, professor of clinical surgery in the College of Physicians and Surgeons, Kansas City.—Dr. Carl Horstmann, extraordinary professor of ophthalmology in Berlin, aged 64. He was formerly assistant to Professor Schweigger, and studied in many foreign hospitals in Holland, England, and France. He published numerous papers connected with ophthalmology.

THE NATIONAL INSURANCE ACT.

THE PROPOSED CONFERENCE WITH THE INSURANCE COMMISSIONERS.

ON Jan. 24th the National Insurance Commissioners for England announced, through the Assistant Secretary to the Joint Committee, their intention to take the earliest opportunity of personally conferring with representatives of the chief sections of the community specially concerned, in order to bring the Insurance Act into operation. With a view to obtaining in this manner suggestions from representatives of the medical profession on certain important questions of preliminary procedure, the Joint Committee of the Commissioners for England, Scotland, and Wales have made arrangements for a conference to-day (Friday, Feb. 2nd). The point specially indicated for discussion was the selection of medical members of the Advisory Committee to be consulted by the Commissioners in the framing of regulations. The letter of invitation also suggested that the Commissioners would welcome the views of the medical representatives at the conference upon other matters of procedure in bringing the Act into operation. We understand that invitations to the conference have been addressed to the following medical bodies: the General Medical Council, the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Scottish Central Council, the National Medical Union, the Reform Committee of the British Medical Association, and the Imperial Medical Reform Union. The Royal College of Physicians of London has decided not to accept the invitation, an example that has been followed by the Royal College of Surgeons of Edinburgh and the Council and the Reform Committee of the British Medical Association.

A WELSH MEDICAL COUNCIL.

We understand that it is intended to form a Welsh Medical Council, primarily through the machinery of the British Medical Association, so that the requirements of the profession in Wales may be formulated for the comprehension of the Welsh Insurance Commissioners. The leaders in the movement feel strongly that a united action with the Commissioners will be more effective than local representations to Local Insurance Committees. A meeting of Welsh medical men will be held at the Raven Hotel, Shrewsbury, at 2 P.M. on Friday, Feb. 9th, when resolutions will be proposed affirming the feeling of the meeting and ensuring that the medical profession in Wales will not work under the Act unless their rights are duly recognised. The Council will nominate an executive to carry on correspondence with the Welsh Commissioners, and to a great extent may be considered a parallel body to the Scottish Central Council, described in our columns last week.

RECOMMENDATIONS OF THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

At the quarterly meeting of the Council of the British Medical Association held on Wednesday, Jan. 31st, the Council's report to the Association on the National Insurance Act was considered and passed for circulation among the members. The report includes a record of the action taken by the Council to give effect to the instructions of the Representative Body; a summary of the position that now confronts the medical profession under the Act; and the conclusions and recommendations of the Council. The latter are as follows:—

I. That the Council be instructed to press on the Government and the Commissioners the further conditions necessary for securing the requirements of the profession.

II. That the Council be instructed to notify the Insurance Commissioners that no negotiations will be entered into with

any Insurance Committee until the Representative Body is satisfied that the requirements of the profession are conceded.

III. That the Council be instructed, as soon as possible after the issue of the regulations by the Insurance Commissioners, to submit a report thereon to the Divisions and the Representative Body.

IV. That the Council be instructed to make all necessary arrangements for the appointment of provisional Medical Committees in every insurance area to safeguard the interests of the profession, without prejudice to the question of whether these Committees shall later accept "recognition" as statutory Local Medical Committees.

V. That the Council be instructed to take steps to organise the profession so as to secure that, failing the provision of adequate remuneration of medical practitioners under the National Insurance Act, no contract practice appointment for attendance upon insured persons shall be held at a lower rate than that which may be agreed upon by the Representative Body as adequate.

VI. That a State Sickness Insurance Committee be appointed to consider and report to the Council on all matters connected with the National Insurance Act; that the committee consist of (*a*) 12 members elected by the Representative Body, (*b*) 12 members elected by the Council, (*c*) two members nominated by the Association of Registered Medical Women; (*d*) the *ex-officio* members; and that the committee be empowered to add to its numbers for special purposes not more than four additional members.

These recommendations are submitted by the Council for the consideration of the divisions of the Association prior to the next meeting of the Representative Body. The Council's report of the future action to be taken by the Association will be considered at a Special Representative Meeting which is announced to be held at the Guildhall, London, on Tuesday, Feb. 20th, at 10 A.M., and on Wednesday, Feb. 21st, in the Court of Common Council Chamber.

BRITISH MEDICAL ASSOCIATION REFORM COMMITTEE.

The provisional executive of the Reform Committee of the British Medical Association, whose manifesto we printed in our issue of Jan. 20th, has issued through its honorary secretary, Mr. P. C. Raiment, a letter to medical practitioners, dated Jan. 29th, which says:—

> You will probably agree that it is only by a properly organised effort, acting on a common basis, that there is any hope of securing the alterations in the National Insurance Act which are necessary if the profession is to obtain its minimum requirements with any security, and with this object I venture to ask if you will become a member of the Reform Committee. The committee believe that no effectual and permanent security can be obtained under Regulations, which can be rescinded as easily as they are made by the Insurance Commissioners; and, therefore, it is felt that only by an Act of Parliament embodying the six cardinal points can any satisfactory solution be reached.
>
> In order that the necessity for this may be impressed upon the Council of the British Medical Association, it is proposed that definite resolutions should be moved in each division of the Association instructing the Representatives to support the following motion at the Representative meeting on Feb. 22nd, viz.: This Representative Meeting directs the Council to inform, in plain and unmistakable language, the Commissioners appointed under the Insurance Act, 1911, that unless the six cardinal points as originally formulated by the British Medical Association be embodied in a Bill amending the Insurance Act, 1911, which shall become law in the next session of Parliament; and unless, in the meantime, these six points be incorporated in the Regulations to be issued by the Commissioners in such a manner as shall be effectual and permanent until such amending Act is passed, it is the intention of the British Medical Association to call upon all its members and upon all other medical practitioners to decline to form panels or undertake any other medical duties which may be assigned to them under the Act, in conformity with the undertaking which has already been signed by over 25,000 medical practitioners.

A copy of the manifesto is enclosed with Mr. Raiment's letter, and medical men who are in agreement with the objects outlined in the two communications are asked to subscribe 5*s.* and to fill in a form of application for membership of the British Medical Association Reform Committee. The form of application is worded to include not only those practitioners who are members of the British Medical Association, but also those who intend to become members of the Association. The question thus arises as to whether the Reform Committee can quite substantiate its claim to the full title which it has assumed. The address of the Reform Committee of the British Medical Association is 29, Old Queen-street, Westminster, S.W., not 129, as was stated in our last issue.

THE BIRMINGHAM COMMITTEE.

We learn that the practitioners of Birmingham have formed an emergency committee outside the local divisions of the British Medical Association with the following objects:—

1. To adopt and to advocate the policy of discontinuing negotiations with the Government and Commissioners, and of refusing to take any part in administrative or medical work under the Act, as under it the demands of the profession were not, and could not be, conceded.
2. To take all possible steps to ensure that this policy be adopted by the British Medical Association both locally and centrally.
3. To formulate what they consider should be the *minimum* requirements of the profession, should the Government desire to amend the present Act.

The committee disclaims hostility to the Association, and numbers among its members the representative of the Birmingham Branch on the Council of the Association and the representative of the Birmingham Central Division on the Representative Body. The committee has decided not to amalgamate at present with the British Medical Association Reform Committee, with which it has been in correspondence.

The honorary secretary of the Wandsworth Division of the British Medical Association asks us to state that the meeting of Wandsworth medical men on Jan. 22nd, referred to in our last issue, was not technically a meeting of the Wandsworth Division.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Paul Preiswerk has been recognised as *privat-docent* of Odontology.—*Berlin:* Professor Theobald Smith, of Harvard University, is giving a special course of lectures, open to students of all faculties, on Parasitism and Disease.—*Cracow:* Dr. Johann Piltz has been promoted to the chair of Psychiatry and Neurology.—*Christiania:* Madame Marie Kjölseth has received the gold medal of the University for her researches in Pathological Anatomy.—*Bonn:* Dr. O. von Franqué, professor in Giessen, has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. Fritsch retired.—*Dresden:* Dr. Rietschel, Director of the Sucklings' Home, and Dr. Galewsky, an eminent dermatologist, have been granted the title of Professor.—*Erlangen:* Dr. Hermann Euler, *privat-docent* of Odontology, has been granted the title of Extraordinary Professor.—*Freiburg:* Dr. August Weismann is retiring at the close of the winter session from the chair of Zoology.—*Hanover:* Dr. Becker, Oberarzt of the Surgical Clinic in Rostock, has been appointed Director of the Children's Hospital.—*Lemberg:* Dr. Heinrich von Halban has been promoted to the chair of Psychiatry and Neurology.—*Lyons:* Dr. T. Lépine, *agrégé*, has been appointed Clinical Professor of Mental Diseases in succession to Dr. Pierret.—*Munich:* Dr. Rullmann, of Darmstadt, has been granted the title of Professor.—*Münster:* Dr. Rammstedt, a Military Surgical Specialist, has been granted the title of Professor.—*Strasburg:* Dr. Bartels, *privat-docent* of Ophthalmology, and Dr. Schickele, *privat-docent* of Gynæcology, have been granted the title of Professor.—*Würzburg:* The large Rinecker gold medal has been awarded to Dr. Rubner, Director of the Berlin Physiological Institute.

ROYAL FREE HOSPITAL.—The Earl of Sandwich presided at the recent meeting of the committee of management of the Royal Free Hospital, at which the following resolutions were passed:—

> That the committee of management desire to offer their cordial congratulations to Miss Eleanor Davies-Colley, M.D., B.S. Lond., upon her admission to the Fellowship of the Royal College of Surgeons of England. Miss Davies-Colley being the first lady to attain this position the committee appreciate the distinction gained by the Medical School of the Royal Free Hospital through her achievement.
>
> The committee also desire to endorse the congratulations which the Board rendered in 1909 to Mrs. Haslam (*née* Miss I. Woodward), M.D. Lond., who, after receiving a medical education at the London School of Medicine for Women and the Royal Free Hospital, was admitted to membership of the Royal College of Physicians of London, being the first lady to receive this diploma.

It was also reported that the Cordwainers' Company will present a gold medal to the nurse who shall obtain the highest number of marks at the annual examination.

BRITISH MEDICAL BENEVOLENT FUND GUILD.—A drawing-room meeting of this guild was held at 100, Harley-street, London, W., on Jan. 25th, to meet the Lady Mayoress and to consider the extension of the guild. Fifteen ladies

have offered to work in making the charity better known, taking the metropolitan boroughs (with sub-divisions) as the basis of the scheme. As a result of the meeting 11 boroughs will be systematically worked, and it is hoped that very shortly the whole 29 will be visited. The ladies will work with Mrs. H. H. Clutton, 3, Park-square, London, N.W., who has consented to be chief secretary and organiser, and a date is to be arranged when the workers and friends of the guild will meet by invitation of the Lady Mayoress at the Mansion House.

THE HUNTERIAN SOCIETY.—The annual oration of the Hunterian Society will be delivered at the London Institution, Finsbury-circus, E.C., by Dr. T. Glover Lyon, on the Cure of Consumptives, a Review and a Forecast, on Wednesday evening, Feb. 14th, at 9 P.M. It would much facilitate the arrangements for the anniversary dinner if those Fellows who intend to be present would signify the same to the honorary secretaries, Dr. A. P. Gibbons, 17, Finsbury-circus, E.C.; and Dr. A. C. Jordan, 11, Bentinck-street, W.

TWELFTH CONGRESS OF THE GERMAN SOCIETY FOR ORTHOPÆDIC SURGERY.—This Congress will take place in Berlin (Langenbeckhaus, Ziegelstrasse, 10 and 11) on April 9th, 1912, the day before the meeting of the German Surgical Society. It will be opened at 9 A.M. The principal subject for discussion will be the Treatment of Infantile Paralysis, by Professor Dr. Paul Krause, of Bonn, and Professor Dr. Fritz Lange, of Munich. Dr. H. Gocht, of Halle a.S., is the President for the year 1912. Preparations, apparatus, and instruments for demonstration are to be addressed to Herr Melzer, Langenbeckhaus, Ziegelstrasse, 10/11, Berlin, N., and applications in respect to membership to Professor Dr. Joachimsthal, Genthinerstrasse, 16, Berlin, W.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner of the West London Medico-Chirurgical Society will be held in the Wharncliffe Rooms, Hotel Great Central, on Thursday, Feb. 8th, at 7.30 for 8 P.M.

A LECTURE on "Malady and Melody: or the Influence of Music in the Healing Art," will be delivered by Dr. G. Norman Meachen, in the Vestry Hall of St. Paul's Church, Canonbury, N., on Tuesday evening next, Feb. 6th, at 8 o'clock. Miss Florence Holdernesse, among others, has kindly consented to supply vocal illustrations.

CENTENARIANS.—Mrs. Annis Moore, of Plymouth, recently celebrated the anniversary of her 101st birthday, as also did Miss Ann Hutchings, an inmate of the Wellington Workhouse Infirmary, Somerset.

UNIVERSITY COLLEGE HOSPITAL.—Sir Ernest Hatch has accepted the office of treasurer of the corporation of University College Hospital and Medical School.

Columbia University Lectures. Scientific Features of Modern Medicine. By Frederic S. Lee, Ph.D., Dalton Professor of Physiology, Columbia University. Price $1.50 net, or 6s. 6d. net.

FABIAN SOCIETY, 3, Clement's Inn, Strand, London, W.C.

Fabian Tract No. 160. A National Medical Service. By F. Lawson Dodd, M.R.C.S., L.R.C.P. Lond., L.D.S., D.P.H. Eng. Published and sold by the Fabian Society. Price 2d.

FISCHER, GUSTAV, Jena.

Handbuch der Pathogenen Mikroorganismen. Herausgegeben von Dr. W. Kolle und Dr. A. von Wassermann. Zweite vermehrte Lieferung (Bd. I., Bogen 16-25). Price M.5. (Band IV., Bogen 1-8). Price M.5. (Das Handbuch erscheint in etwa 40 Lieferungen: Preis jeder Lieferung 5 mark.)

Handbuch der Vergleichenden Physiologie. Herausgegeben von Hans Winterstein in Rostock. Siebzehnte Lieferung. Band I. Physiologie der Körpersäfte. Physiologie der Atmung. Erste Hälfte. Bogen 11 bis 20. Price M.5.

Achtzehnte Lieferung. Band II. Physiologie des Stoffwechsels. Physiologie der Zeugung. Erste Hälfte. Bogen 72 bis 98, nebst Titel und Inhalt. Price M.5.

Neunzehnte Lieferung. Band III. Physiologie des Energiewechsels. Physiologie des Formwechsels. Erste Hälfte. Bogen 1 bis 10. Price M.5.

Handbuch der Gesamten Therapie. In sieben Bänden. Herausgegeben von Dr. F. Penzoldt und Dr. R. Stintzing. Vierte umgearbeitete Auflage. Zweiundzwangiste Lieferung. Price M.4.50. (Preis des vollständigen Werkes: 100 Mk., geb. 117 Mk. 50 Pf.)

Lehrbuch der Therapie innerer Krankheiten. Für Aerzte und Studierende. In zwei Bänden. Herausgegeben von Dr. Paul Krause und Dr. Carl Garrè. Zweiter Band. Spezielle Therapie innerer Krankheiten. Price, paper, M.10.50; bound, M.11.50.

Die Krankheiten des Mundes. Von weil J. Von Mikulicz und W. Kümmel. Dritte Auflage. Neu bearbeitet von Werner Kümmel, Direktor der Universitätsklinik für Ohren-, Nasen-, und Kehlkopfkranke in Heidelberg. Mit Beiträgen von Prof. A. Czerny, Direktor der Universitätskinderklinik in Strassburg i.E., und Prof. J. Schäffer in Breslau. Price, paper, M.9; bound, M.10.

Das Bakterien-Anaphylatoxin und seine Bedeutung für die Infektion. Von Dr. Hermann Dold, I. Assistent am Institut für Hygiene und Bakteriologie der Universität Strassburg. (Aus dem Institut für Hygiene und Bakteriologie der Universität Strassburg; Direktor: Geheimrat Professor Dr. Uhlenhuth.) Price M.2.80.

Sammlung Anatomischer und Physiologischer Vorträge und Aufsätze. Herausgegeben von Prof. Dr. E. Gaupp und Prof. Dr. W. Trendelenburg. Heft 17 (Zweiter Band, Heft 4). Physiognomie und Schädel. Von Dr. med. H. von Eggeling, a.o. Professor und Prosektor an der Anatomischen Anstalt der Universität Jena. Price M.1.50; subscription price, M.1.20.

LAURIE, T. WERNER, Clifford's Inn, Fleet-street, London, E.C.

New Zealand, the Country and the People. By Max Herz, M.D. Price 12s. 6d. net.

LONGMANS, GREEN, AND CO., London, New York, Bombay, and Calcutta.

A Dictionary of Applied Chemistry. By Sir Edward Thorpe, C.B., LL.D., F.R.S., Professor of General Chemistry and Director of the Chemical Laboratories of the Imperial College of Science and Technology, South Kensington, London. Assisted by Eminent Contributors. In five volumes. Vol. I. Revised and enlarged edition. Price 45s. net.

Heredity and Society. By William Cecil Dampier Whetham, M.A., F.R.S., Fellow and Tutor of Trinity College, Cambridge, and Catherine Durning Whetham, his Wife. Price 6s. net.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, 9, Conduit-street, Regent-street, London, W.

Modern German Hospital Construction. By William Milburn, Jun., A.R.I.B.A., Henry Saxon Snell Prizeman, 1908, Godwin Bursar, 1910. Price 3s. 6d. net.

SAUNDERS (W. B.) COMPANY, Philadelphia and London.

Nervous and Mental Diseases. By Archibald Church, M.D., Professor of Nervous and Mental Diseases and Medical Jurisprudence in the Northwestern University Medical School (the Chicago Medical College), Chicago; and Frederick Peterson, M.D., Ex-President of the New York State Commission in Lunacy, Professor of Psychiatry, Columbia University. Seventh edition, thoroughly revised. Price 21s. net.

Operative Obstetrics, including the Surgery of the Newborn. By Edward P. Davis, A.M., M.D., Professor of Obstetrics, Jefferson Medical College. Price 24s. net.

A Text-book of Medical Chemistry and Toxicology. By James W. Holland, A.M., M.D., Professor of Medical Chemistry and Toxicology, and Dean, Jefferson Medical College, Philadelphia. Third edition, thoroughly revised. Price 15s. net.

A Text-book of the Practice of Medicine. By James M. Anders, M.D., Ph.D., LL.D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College, Philadelphia. Tenth edition, thoroughly revised. Price 24s. net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BALL, W. GIRLING, F.R.C.S., L.R.C.P. Lond., has been appointed Surgeon to the Alexandra Hospital for Hip Disease.

CATHCART, J., M.B., Ch.B. Edin., has been appointed Assistant Medical Officer to the Barnes Convalescent Home, Cheadle.

COOMBE, RUSSELL, F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Budleigh Salterton (Devon) Cottage Hospital.

CORE, D. E., M.D. Vict., M.R.C.P. Lond., has been reappointed Resident Medical Officer at the Manchester Royal Infirmary.

EDDISON, F. R., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Bedale District of the county of Yorks, North Riding.

HUDSON, E. P., L.D.S. Eng., has been appointed Dental Surgeon to the Royal Free Hospital.

HUGHES, E. E., M.B., Ch.B. Vict., has been reappointed Resident Medical Officer at Barnes Convalescent Home, Cheadle.

JAMES, A. H., M.D. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Blaenavon District of the county of Monmouth.

JONES, E. H., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Northampton General Hospital.

LEGATE, R. L., L.R.C.P. & S. Edin., L.A.H. Dub., has been re-appointed Medical Officer of Health for the Christchurch Urban District of Bournemouth.

MARSDEN, J. A., M.R.C.S., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Hipperholme District of the county of Yorks, West Riding.

MATTHEWS, NEWTON, M.B., Ch.B. Vict., has been appointed House Physician at the Manchester Royal Infirmary.

NICHOLL, ERNEST EDWARD, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth and Ninth Districts by the South Molton (Devon) Board of Guardians, and Medical Officer for the High Bray District by the Barnstaple (Devon) Board of Guardians.

ORRIN, HERBERT CHARLES, F.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Surgeon to the Newton Abbot (Devon) Hospital.

PATEY, WALTER, M.D., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Newton Abbot (Devon) Hospital.

ROBINS, J. N., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Chatham District of the county of Kent.

RUSSELL, JAMES WILLIAM, M.D., B.C. Cantab., F.R.C.P. Lond., has been appointed Honorary Physician to the Birmingham General Hospital.

SEAL, PHILIP HENRY, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the South Molton (Devon) Union Workhouse.

TURNER, A., L.R.C.P. Edin., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Kelvedon District of the county of Essex.

TYLECOTE, F. E., M.D. Vict., M.R.C.P. Lond., has been reappointed Medical Registrar to the Manchester Royal Infirmary.

WEBB, WILLIAM TUDOR, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third, Fifth, and Tenth Districts by the Kingsbridge (Devon) Board of Guardians, and Medical Officer of Health for the Kingsbridge Rural District Council.

WESTMACOTT, FREDERIC H., F.R.C.S. Eng., has been appointed Assistant Surgical Officer to the Aural Department of the Manchester Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Resident Surgical Officer. Salary £100 per annum, with apartments, board, and attendance.

BRIDGWATER HOSPITAL.—House Surgeon for six months, unmarried. Salary at rate of £100 per annum, with board, lodging, and washing.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with apartments, board, and laundry.

BRITISH LYING-IN HOSPITAL, Endell-street, W.C.—Resident Medical Officer. Salary at rate of £50 per annum, including board, lodging, and washing.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—Assistant Pathologist. Salary £350 per annum.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—House Surgeon, unmarried. Salary £80 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary £150 per annum, with board, &c.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

CROYDON GENERAL HOSPITAL.—Junior House Surgeon. Salary £75 per annum, with board, laundry, and residence.

EASTBOURNE, COUNTY BOROUGH OF.—Assistant School Medical Officer and Assistant Medical Officer of Health. Salary £250 per annum.

GLOUCESTER COUNTY ASYLUMS.—Assistant Medical Officer, unmarried. Salary £150 per annum, with rooms, rations, laundry, and attendance.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Physician.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Clinical Pathologist and Bacteriologist. Salary 100 guineas per annum.

LARBERT, STIRLING DISTRICT ASYLUM.—Junior Assistant Medical Officer. Salary £130 per annum, with board, &c.

LEICESTER, PARISH OF.—Resident Second Assistant Medical Officer. Salary £130 per annum, with rations, apartments, and washing.

LONDON COUNTY COUNCIL.—Deputy Medical Officer of Health and Deputy School Medical Officer of the County of London. Salary £1000 per annum.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MIDDLESEX HOSPITAL, W.—Assistant Medical Officer to the Electrical Department. Salary £50 per annum.

MILDMAY MISSION HOSPITAL, Bethnal Green, E.—House Surgeon, unmarried. Salary for first six months, as Junior, at rate of £70 per annum, and then, as Senior, £80 per annum, with board, residence, and laundry.

NEWCASTLE-ON-TYNE HOSPITAL FOR SICK CHILDREN.—Honorary Ophthalmic Surgeon, Honorary Assistant Surgeon, and Honorary Assistant Physician.

OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with quarters, board, and laundry.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT, Bromley, E.—Third Assistant Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, residence, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, N.E.—House Surgeon, for six months. Salary at rate of £80 per annum, with board, residence, and washing.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Honorary Assistant Surgeon. Also Surgical Registrar. Salary £105 per annum.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Appointments.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Senior Resident Medical Officer, unmarried. Salary at rate of £100 per annum, with board, residence, and laundry. Also Surgeon-in-Charge of X Ray Department. Salary £50 per annum.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer, unmarried. Salary £105, with residence, attendance, and midwifery fees.

SALFORD COUNTY BOROUGH.—Assistant to Medical Officer of Health. Salary £250 per annum.

SALFORD ROYAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £50 per annum, with board and residence.

SHEFFIELD, JESSOP HOSPITAL FOR WOMEN.—Assistant House Surgeon. Salary £40 per annum.

SHEFFIELD UNIVERSITY.—Demonstrator in Experimental Physiology and Pharmacology. Salary £200 per annum.

SHERWOOD FOREST, RANSOM SANATORIUM FOR CONSUMPTIVES, near Mansfield, Notts.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and washing.

STAFFORD, COTON HILL LUNATIC HOSPITAL.—Assistant Medical Officer. Salary £150 per annum, with residence, board, and laundry.

WALSALL AND DISTRICT HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Also House Physician. Salary £90 per annum, with board, residence, and laundry.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Swineford, in the county of Mayo; at Luddenden, in the county of Yorks, West Riding; at Romford, in the county of Essex; at South Molton, in the county of Devon; and at Virginia, in the county of Cavan.

Births, Marriages, and Deaths.

BIRTHS.

DUDGEON.—On Jan. 28th, at Ashley-gardens, S.W., the wife of Leonard S. Dudgeon, F.R.C.P. Lond., of a daughter.

MOON.—On Jan. 25th, at Green-street, W., the wife of R. O. Moon, M.D., of a daughter.

NEWLAND.—On Jan. 22nd, at "Layston," Bromley, Kent, the wife of H. G. Newland, L.D.S., of a daughter.

MARRIAGES.

COWEN—WATTS.—On Jan. 27th, at St. Stephen's, Gloucester-road, S.W., Edward George Huxley Cowen, R.A.M.C., to May Eva, eldest daughter of Mr. and Mrs. A. C. Watts, of Sutton, Surrey.

MCCULLY—CLEATON.—On Jan. 24th, at St. Stephen's Church, Hampstead, Donald McCully, M.R.C.S., L.R.C.P., to Gwendolen, only daughter of E. R. Cleaton, "The Pryors," Hampstead.

DEATHS.

DUKE.—On Jan. 30th, at Southwick, Sussex, Allen A. Duke, M.D. Edin., suddenly, of cardiac failure, aged 75.

HOLMES.—On Jan. 28th, at Westgate-terrace, London, S.W., Robert Andrew King Holmes, Lieutenant-Colonel Indian Medical Service.

OSWALD.—On Jan. 24th, at Clapham-road, S.W., J. W. J. Oswald, M.D., F.R.C.S. Edin., in his 81st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"WILL THE EDITOR KINDLY——?"

A WEEK never passes without some queer communication or illiterate request reaching the offices of THE LANCET. Such letters from non-medical readers naturally deal for the most part with the ailments of the writers or of their friends, and the majority of these seek our advice on the subject of a "Specialist" or a "Cure." A few weeks ago we were requested to name "a specialist in von Recklinghausen's disease," and this week we are asked if we "know of any cures for a serious complaint called sarcoma of the small 'spindle cell type." We are often tempted to print the more unusual of these questions, but in many cases it would be cruel to do so. Often the stranger the request the more pathetic is the ignorance displayed. But there are other communications equally ignorant and illiterate which are written in a different spirit and deserve to be held up to ridicule. Uneducated cranks of every kind write to us to ventilate their views, and their obvious simplicity and sincerity forbid us to pillory them by publication. It is only when they are abusive or mischievous that we do so. The following letter comes from one who calls himself a "Hydropathist":—

To the Editor of THE LANCET.

DEAR SIR,—Modern Science teaches there is no infectious disease none whatever. But you have not got it and we can never have it, for we have medical council which governs medical practice all the time. And in medical practice there is no cure for fever or any other infectious disease so the poor patient has to suffer like a dog. Fever must run its course is a fallacy of the most dangerous type. And is unscientific and unreliable as it generates matures and distributes millions of germs to make other cases of infectious diseases. Can you wonder that the germs get mixed and patients contract other diseases however careful the Physicians and Nurses might be.

In Hydropathy there is no infectious disease, we cure fever without poisonous drugs. We cure fever before it has a name, the Medical man must let fever run for at least two days, so as to know what fever it is, and fever can be cured in 48 hours without complications or anxiety. It is not Christian Science where they pray over the Sick and anoint the head with Oil. But Medical practice is worse then that as they can do nothing in Fever cases.

Yours Very Truly,

Toronto, January 1, 1912. JOSEPH BRADLY, Hydropathist.

Undoubtedly Mr. Bradly might give very evil counsel to people unable to detect his essential silliness.

AN APPEAL FOR INSTRUMENTS.

To the Editor of THE LANCET.

SIR,—I have been asked by Archdeacon Pugh, of Yale, B.C., to appeal to those members of the profession who have any surgical instruments for which they have no further use and are willing to give to a charitable object, that they would send any such instruments to him for use in the Indian hospital at Yale.

I am, Sir, yours faithfully,

Harley-street, Jan. 29th, 1912. RICHARD LAKE.

PS.—Instruments to be sent to Archdeacon Pugh, 4, Dean's Yard, Westminster.

"COMPENSITIS."

Mr. Alex. Mercer, M.R.C.S., L.R.C.P., writes under the above title:—"This term may be applied to a form of neurosis, with characteristics of its own, which has been manufactured by the machinery of the Workman's Compensation Act. Though distinct from malingering, there are border-line cases which are difficult to differentiate; and, indeed, the two conditions may occur together. It may also be divided from hysteria, which, generally speaking, presents an unstable mental condition previous to the accident, the latter merely being an episode in the course of the disease. In certain temperaments it is difficult to tell where the hysteria begins and the malingering ends, so closely are the two conditions often combined. Here, however, I am attempting to keep compensitis in a category of its own. It may be divided into three types. 1. The litigation type. In this exaggeration is the main characteristic. It follows an injury from which, if the Act were non-existent, an average person would be eager to recover. The usual history is that the patient's mind is first directed to the law by friends or relations. Unfortunately, there are certain of the legal profession who, to put it tersely, do the rest. The anticipation of the pending litigation exaggerates the injury in the patient's mind. Such cases speedily get well when the case is settled. 2. The neurotic type. Here the injured person is what is termed variously by the medical practitioner a 'general complainer' or a 'chronic.' An accident produces a state of mind akin to gratification. The individual may be out of ailments at the time, or existing ailments are promptly overweighted by the injury. These persons are never perfectly happy unless they appear miserable. This state of the nervous system is only acquired by considerable experience. They are apt to put little stress on the actual injury, but all their ailments have (in their minds) undoubtedly sprung from it. They often say, 'I never ailed in my life until this accident.' 3. The neurasthenic type. Patients of this type may never have been ill, or had an accident, or suffered pain before. They have heard of such things, but the reality comes as a shock to them. The injury upsets the normal equilibrium of the nervous system, and they work themselves up into a neurasthenic state. A common symptom is the complaint of various pains in different parts of the body, often springing from the seat of injury. The condition can be differentiated from neuritis in that there are no trophic or vaso-motor disturbances, and the pains follow no definite nerve course. There may be wasting of muscles from prolonged disuse. The two latter types represent a very large number of cases that daily come under the notice of medical referees and are a class in themselves. From a legal point of view they are usually placed amongst the 'unfit-for-work's,' and often the comfortable opinion is expressed that 'they will never be fit for work as long as they live.' This view in certain individuals seems to take such root that conviction becomes a certainty. As long as the condition is one of pure compensitis it is difficult, from a medical point of view, to say that the former work can be resumed, but in a good percentage of cases it is associated with malingering, or the latter takes its place. These are the cases that need all one's experience and knowledge."

WETTING THE FINGER.

To the Editor of THE LANCET.

SIR,—I see that you have been ventilating in your columns objections to the horrible practice of wetting the finger, which is also done in opening paper bags, &c., in shops. Far the most offensive instance is to be observed in tea-shops, where the girls behind the counter almost invariably wet the finger to detach the edges at the mouth of a bag and then *with the same finger* pick up a bun or cake to put in the bag! So offensive is it that I have altogether given up buying buns. Public opinion is the main thing, but until it is educated to repudiate altogether such practices the large employers of such labour—i.e., Messrs. Lyons and the A.B.C. directors—could do much by strictly enforcing prohibition. If they would at the same time provide small forks or tongs for touching cakes, and enforce the use of them on their employees, they would be doing great service to the more fastidious of their customers. Some of the girls seem to take a positive delight, not only in fingering, but in handling the cakes well over in the palm, and woe be to the customer who dares to protest! One of the worst instances of the previously mentioned nuisances I have ever known was when I bought some lozenges in a druggist's shop this morning, and the assistant actually licked up the envelope before handing it to me! These shops are usually above reproach in this respect.

I am, Sir, yours faithfully,

Hammersmith, W., Jan. 26th, 1912. G. E. MITTON.

*** In the annotation on Hygiene and the Tube Booking Clerk, referred to above by our correspondent, we suggested that if the unmoistened finger is placed at a mechanical disadvantage the difficulty might be met by a damping-pad beside each pigeon-hole. We now read in a daily paper that this is done on the Central London Railway. But the moistened finger has not been supplanted by the wet pad throughout the Tube booking-offices of London.—ED. L.

J. S.—We believe that most authorities would regard in-breeding to such an extent as inadvisable in the interests of the next generation.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Feb. 2nd-6th (London, Crystal Palace).—International Bird Show of the London and Provincial Ornithological Society.
" 13th-14th (London).—Central Poor-Law Conference.
March 7th-11th (Berlin).—Thirty-third Balneological Congress.
March 23rd-April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st-7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th-13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th-15th (Johannesburg).—Thirteenth South African Medical Congress.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W (temporary address during building of new house).

TUESDAY.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.

Laboratory Meeting at the Pathological Department, St. Bartholomew's Hospital, E.C.

Dr. M. H. Gordon: Slides illustrating Histology of Cord in Acute Poliomyelitis.

Dr. J. F. Gaskell: The Development of a Longitudinal Muscular Coat in the Renal Artery.

Dr. A. E. Gow: The Occurrence of Albumin in the Cerebro-spinal Fluid.

Dr. J. E. H. Roberts: Tumours of Tendon Sheaths.

Dr. F. M. Andrewes: A Case of Syphilitic Disease of the Aortic Intima.

Dr. F. M. Andrewes and Dr. A. E. Gow: The Simulation of Spirochætes by Fibrin Filaments under Dark Background Illumination.

FRIDAY.

GENERAL MEETING OF FELLOWS at 4.45 P.M.

Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: James Galloway, C. H. Fagge): at 8.30 P.M.

Cases:

Mr. F. J. Steward: Successful Excision of Epithelioma of Lower End of Pharynx.

Mr. W. H. Battle: Mikulicz' Disease.

Dr. F. Langmead: Anomalous Œdema.

Paper:

Dr. Wilfred Harris and Mr. W. H. Clayton Greene: A Case of Congenital Absence of the Left Half of the Diaphragm Simulating Pneumothorax.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—9 P.M., Dr. A. E. Garrod: Glycosuria. (Lettsomian Lecture I.)

RÖNTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

TUESDAY.—8.15 P.M., Hon. R. J. Strutt: After-glow in Vacuum Discharge Tubes.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—8 P.M., Dr. L. Hill and Dr. M. Flack: The Influence of Ozone in Ventilation.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Cases will be shown by Mr. R. Doyne and Mr. C. Wray.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY, Johnston's Rooms, 6, Broadway, Wimbledon.

FRIDAY.—9 P.M., Mr. J. S. Joly: Recent Advances in the Diagnosis and Treatment of Syphilis and Gonorrhœa.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. Willmott Evans: Clinique (Skin). 5.15 P.M. Lecture:—Mr. A. Lawson: Glaucoma (illustrated by lantern slides).

TUESDAY.—4 P.M., Dr. C. O. Hawthorne: Clinique (Medical). 5.15 P.M., Lecture:—Mr. H. A. Whitelock (Oxford): The Injuries to the Extensor Apparatus of the Knee-joint.

WEDNESDAY.—4 P.M., Mr. E. R. Carling: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. J. Morrison: Use of Forceps during the Second Stage of Labour.

THURSDAY.—4 P.M., Mr. R. Howard: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. J. Smith: Diet in Enteric Fever.

FRIDAY.—4 P.M., Dr. Dan McKenzie Clinique (Ear, Nose, and Throat). 5.15 P.M., Lecture:—Dr. W. Wingrave: Pathology of Discharges.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M. Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Symptoms and Treatment of Gall Stones.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: Clinical (Urinary Surgery).

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture III.)

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture III.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. H. Cole: Manic Depressive Insanity.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

A Lecture

ON

CERTAIN CHRONIC GLANDULAR ENLARGEMENTS.

Delivered before the Greenock Faculty of Medicine on Dec. 6th, 1911,

BY WALTER K. HUNTER, M.D., D.Sc. GLASG.,

MUIRHEAD PROFESSOR OF MEDICINE, GLASGOW UNIVERSITY; PHYSICIAN, GLASGOW ROYAL INFIRMARY.

MR. PRESIDENT AND GENTLEMEN,—I have chosen this subject for my lecture, not because I have anything fresh to say regarding the etiology and pathogenesis of the diseases of lymphatic glands, but because I have had under my care recently a number of cases of glandular enlargement in which the diagnosis was a matter of no little difficulty, and which may serve, therefore, to illustrate some of the problems which present themselves in dealing with other cases of a similar kind.

CLASSIFICATION.

In proceeding to investigate any case of glandular enlargement it is well to have in one's mind some sort of classification of the various diseases to which lymphatic glands are subject. Such a classification should, if possible, be based on the etiology of the various enlargements; but as the specific virus in so many of these diseases is still unknown it seems more convenient, in the meantime at least, to group the glandular enlargements according to their histological anatomy.

The lymphatic gland, you will recollect, consists of a framework of connective tissue in which masses of lymphoid cells are arranged in regular groups. Each gland has a capsule of firm connective tissue from the inner surface of which trabeculæ are given off, and which converge towards the hilus of the gland: the spaces between the trabeculæ are filled up by a very fine reticular tissue. The lymph follicles appear as rounded nodules at the periphery of the gland, and they send off cord-like aggregations of lymphocytes which anastomose freely and form its medullary portion. Between the collections of lymphoid cells (follicles and follicular cords) lie the lymph sinuses. These spaces are traversed by the cell reticulum, and they and the reticulum are lined with flat, polygonal, epithelioid cells.

The two chief cellular elements, therefore, in the lymphatic gland are: (1) the lymphoid cells; and (2) the cells of the reticulum, with which one includes the epithelioid cells; and most of the primary diseases of glands can be grouped into one of two classes according as it is the lymphoid or the connective tissue elements that are primarily affected.

GROUP I.—HYPERPLASIA OF LYMPHOID CELLS.

In the first group the outstanding morbid change consists of a marked hyperplasia of the lymphoid cells. The follicles are thus greatly increased in size, and overflow, as it were, into the sinuses, which come to be flooded with lymphocytes. The gland on section presents, therefore, the appearance of a homogeneous mass of lymphoid cells with no differentiation into sinus and follicle. Cases with glandular enlargement of this sort have been grouped under the term lymphocytoma; but whilst the glands from such cases have much the same structure histologically, one may find marked differences clinically between the individual cases. In some cases, for example, the glands involved are limited in number, whilst in others the glandular enlargement is widespread. In some the lymphocytes infiltrate the gland capsule, and even invade the surrounding tissues; and in some cases, again, there are lymphocytes to be seen infiltrating the liver, kidneys, and other organs. In almost all the cases the disease tends to be progressive, but in some the growth is so slow as to make such cases really benign. There are, however, all degrees of malignancy to be met with, and cases that have been benign for a long time may ultimately take on a much more active growth.

Some of these cases of lymphocytoma show no change in the characters of the blood. In others, on the other hand, there is a great increase in the number of white corpuscles, and usually the increase is in the lymphocytes. There may, however, be this relative and absolute increase of lymphocytes without the total number of white cells being increased.

Under the term lymphocytoma we include, then, cases of what is called pseudoleukæmia, the lymphatic leukæmias, and the lymphosarcomas, as well as any glandular enlargement due to an overgrowth of the lymphoid elements in the gland. Warthin[1] maintains that these different forms of lymphocytoma are genetically related, that they are, indeed, but different phases of the same disease. And from the histological point of view it is by no means easy to draw a dividing line between the different forms, to distinguish histologically the gland, for example, of a case of lymphatic leukæmia from that of a case of lymphosarcoma. The line to be drawn between these two conditions is not a very definite one, and to make the differentiation more difficult the characters of the blood in lymphosarcoma sometimes assume the appearances met with in lymphatic leukæmia.

GROUP II.—OVERGROWTH OF CONNECTIVE TISSUE ELEMENTS.

In the second group of cases the enlargement depends on an overgrowth in the connective tissue elements of the gland. This hyperplasia may be regarded as inflammatory in nature, the special characters of the reaction depending on the specific virus causing the disease. I must, however, make it clear that we are at present considering only the chronic enlargements of glands, such enlargements as show little tendency to suppuration. A micro-organism by growing in, or passing through, a gland seems to lose some of its virulence, and it may be that it is this attenuation of the virus that determines the chronicity of the growth as well as the limitation of the infection to the lymphatic system.

As in Class I., so here also we may have only one group of glands enlarged, or else the enlargement may involve almost all the glands in the body; all gradations are to be met with between these two extremes.

Perhaps the most striking glandular enlargement in this second group is that seen in Hodgkin's disease (endothelioid type). But there are also cases of tuberculous, or of syphilitic, adenitis which clinically are very difficult to differentiate from Hodgkin's disease, and the same even applies to certain chronic inflammations of glands, infective in origin, but not necessarily always due to any one specific bacterium. This last type of enlargement may be called chronic simple adenitis.

Chronic Simple Adenitis.

Chronic simple adenitis, then, can probably be produced by almost any of the pathogenic micro-organisms of low virulence. The histological process consists of a proliferation of the endothelial cells and cells of the reticulum, with subsequent diffuse and slow fibrosis. The capsule of the gland becomes greatly thickened and infiltrated with cells; the trabeculæ are also thickened and the sinuses disappear. Sometimes to begin with there is a definite hyperplasia in the follicles, but in the later stages the stroma increases to such an extent as entirely to smother the lymphoid elements.

This form of adenitis most commonly affects only one group of glands, but it has been shown that the glandular enlargement may be widespread and simulate very closely Hodgkin's disease.[2]

Tuberculous Adenitis.

In the cases of tuberculous adenitis that resemble Hodgkin's disease there is little tendency to caseation, and the glands ultimately become fibrosed. The tuberculous process usually begins in the lymph follicles where there are to be seen aggregations of epithelioid and giant cells derived from the cells of the reticulum. There is also a hyperplasia of the epithelioid cells of the sinuses in the neighbourhood of the tubercle, and this may give rise to a very diffuse epithelioid tuberculosis with few giant cells and little or no caseation. The lymphoid tissue may be replaced to a considerable extent by this epithelioid growth.

This tuberculous adenitis may affect one group of glands,

[1] Osler and Macrae's System of Medicine, vol. iv., p. 827.
[2] Maladies des Veins et des Lymphatiques, by Widal, Bezançon, and Labbé, p. 117.

or the glandular enlargement may be widespread; the spleen even may become affected.

Syphilitic Adenitis.

Syphilitic adenitis is frequently met with as an early manifestation of secondary syphilis, and the glandular enlargements may be widespread and may persist for years. It is, however, the glandular enlargements of the tertiary stage that are most likely to be mistaken for Hodgkin's disease. Such cases of syphilitic adenitis are rare. Clinically they are difficult to recognise as being syphilitic in origin, and even on histological examination the appearances may resemble very closely those of a chronic tuberculous adenitis.[3] Treatment by iodide of potassium may be used as an aid in clearing up the nature of the adenitis.

Hodgkin's Disease.

Hodgkin's disease has also many of the characters of a chronic inflammation, but it is seldom difficult to distinguish it histologically from a syphilitic or a tuberculous adenitis. In Hodgkin's disease there seems to be an initial hyperplasia of the lymphoid cells with active proliferation of their germinal centres. There is also a hyperæmia of the gland with proliferation of the reticular and endothelial cells. Giant cells are formed and there are many eosinophile cells. The reticulum is increased and forms a network of rather coarse connective tissue in the meshes of which are to be seen a considerable variety of cells—large and small lymphocytes, polynuclear cells, epithelioid cells, plasma cells, eosinophile cells, and mononuclear and multinuclear giant cells. There are frequently also small areas of necrosis sometimes containing fibrin and sometimes polynuclear cells. In the later stages of the disease the gland gets almost completely converted into fibrous tissue. Secondary deposits may be met with in the spleen, liver, kidneys, bone marrow, lungs, intestinal tract, or skin. The growths in Hodgkin's disease do not, however, often invade surrounding tissues, though in some cases they do, almost in the same way as does a malignant tumour.

Secondary Infections.

Now it is to be noted that all these glandular enlargements seem to be peculiarly liable to secondary infections, which may considerably alter the histological appearances. Thus a case of simple adenitis may assume the characters of a tuberculous adenitis or of Hodgkin's disease; and, again, the glands in Hodgkin's disease may show a secondary infection with the tubercle bacillus. Or, yet again, any of the glandular enlargements of Group II. may become replaced by a growth with the histological characters of Group I. Case 3 furnishes an example of this, where what I take to have been a syphilitic adenitis was ultimately replaced by a lymphosarcomatous growth.

Characters of Blood.

There is nothing characteristic in the appearances of the blood in any of the enlargements of Group II. It is true there is very often a secondary anæmia, and sometimes a leucocytosis; but the former may be met with in any debilitating condition, and the latter is probably most often due to secondary infections. Sometimes there is a relative increase of the mononuclear cells, but this is by no means constant.

A Third Group.

A third group of glandular enlargements might be added so as to include tumour growths, and this might be subdivided according as the growth was primary or secondary. Lymphosarcoma is the most common primary tumour growth in glands, but as it seems so closely allied to lymphatic leukæmia it seems more convenient to leave it in Group I. The endothelioma is possibly also a primary growth in glands, but if so it must be very rare. Of the secondary tumour growths cancer is much the most common, but sarcoma and endothelioma may also be found as secondary growths.

ALEUKÆMIC LEUKÆMIA.

The first case I have to describe to you is one of aleukæmic leukæmia, and falls, therefore, to be classed under Group I. The clinical features of the case, however, were those of almost any of the glandular enlargements, and as there was no increase in the number of the white corpuscles the diagnosis rests almost entirely on the differential leucocyte count, which showed the presence of a very large proportion of lymphocytes. I showed blood-films from this patient at a meeting of the Glasgow Medico-Chirurgical Society[4] last winter.[5]

CASE 1.—The patient was a boy aged 13 years. The glandular enlargement was first noticed in January, 1910. The glands all over the body were enlarged but those in the cervical regions most so. During the spring months of 1910 the glands lessened in size, but towards the end of June they seemed to enlarge again. The general health all this time remained unaffected.

I saw the boy for the first time at the beginning of September, 1910, and then he looked strong and robust without any appearance of anæmia. The glandular enlargement was not very considerable, though it was quite noticeable. There were enlarged glands along the line of the sterno-mastoid as well as at the anterior borders of the trapezius. The submaxillary glands were also enlarged, but no individual gland seemed much larger than a marble. Glands of the same size were found in the armpits and in the groins. The spleen was enlarged and extended as low as the level of the umbilicus. The liver was not palpable, and there was no evidence of enlargement of the mediastinal or abdominal glands.

The chief point of interest in the subsequent course of the illness was the alternate increase and diminution in the size of the glands. Thus, by Oct. 14th, 1910, the glandular enlargement in the neck had almost disappeared. Then about the beginning of December the swelling reappeared, and by January the glands were much the same size as on Sept. 1st. There were noted for the first time a large number of small subcutaneous nodules varying in size from a pea to a millet seed, all over both arms, less numerous on the thighs, and scanty on the back. There were also nodules of this sort at the outer end of each eyebrow, and the skin here had a purple, cyanosed tint. Similar nodules were noted in the ocular conjunctiva. Subsequent to this the glands became softer in consistence and again began to lessen in size, and by the middle of February the glandular enlargements as well as the subcutaneous nodules had almost entirely disappeared. Then, yet again, the glands enlarged and by the middle of April the condition was much the same as in January. During the summer the glands again lessened in size but never so much as formerly, and in the late autumn they again became enlarged; by Nov. 11th, 1911, they were nearly as large as ever they had been. The subcutaneous nodules, too, were now very prominent and much the same as formerly noted, though on the face more numerous and of larger size than at any time before. The size of the spleen remained fairly constant and was now very little larger than a year ago.

The patient's general condition during the past year showed considerable variation and the improvement seems to have been more often coincident with the enlargements of the glands than with their diminution in size. For example, at the middle of October, 1910, the patient was pale and disinclined for exertion. A few weeks later he seemed much better and able to run about. Then again in January he was ill, seemed fevered, and was confined to bed for some weeks. He improved during last summer, and was able to be up and go outside; but he was not nearly so robust as at the corresponding time a year before.

Treatment with arsenic was carried out for many months but in a somewhat intermittent manner, as it so often seemed to cause diarrhœa. It is very doubtful if this drug had much to do with the successive diminutions in the size of the glands that I have described.

The blood count was as follows:—

Blood Counts in Case 1.

	Red corpuscles.	White corpuscles.	Hæmoglobin.
Sept. 1st, 1910...	3,950,000 per c.mm....	7,916 per c.mm. ...	85 per cent.
Oct. 14th, ,, ...	3,160,000 ,, ,, ...	2,812 ,, ,, ...	55 ,,
Jan. 9th, 1911 ...	3,500,000 ,, ,, ...	9,000 ,, ,, ...	70 ,,
Feb. 18th, ,, ...	1,724,800 ,, ,, ...	3,000 ,, ,, ...	35 ,,
April 15th, ,, ...	1,932,900 ,, ,, ...	8,910 ,, ,, ...	36 ,,
Nov. 11th, ,, ...	3,200,000 ,, ,, ...	11,250 ,, ,, ...	65 ,,

Differential Counts of White Cells.

	Polynuclear cells.	Lymphocytes.	Eosinophiles.
Sept. 1st, 1910 ...	3 per cent. ...	95 per cent. ...	1·5 per cent.

Nov. 11th, ,, ...	24 ,, ...	69 ,, ...	6 ,,

[3] Loc. cit., p. 123.

[4] Glasgow Medical Journal, February, 1911, p. 134.

[5] N.B.—This patient died on Jan. 12th, 1912.

The individual lymphocytes varied a good deal in size, but the prevailing cell was at least a half larger than a red corpuscle.

A gland was not excised in this patient, and so the diagnosis was not confirmed by histological examination; but the persistent high percentage of lymphocytes seems to leave little doubt that the case is one of lymphatic leukæmia.

ACUTE LYMPHATIC LEUKÆMIA.

The second case[6] I wish to refer to was regarded, up to a few days before death, as suffering from Hodgkin's disease, on the grounds of the glandular enlargements and the absence of any considerable leucocytosis; blood films, however, had not been examined. A differential count when it was made revealed the fact that there were only 2·5 per cent. of polynuclear cells and 97·5 per cent. of mononuclears—mostly lymphocytes; and so the diagnosis had to be altered to that of lymphatic leukæmia.

CASE 2.—The patient was a lad, aged 19, and he had large glandular swellings in the neck, axillæ, and groins. There was also increase of the manubrial dulness, the measurement being 3 inches in transverse diameter. Both liver and spleen were considerably enlarged, the former extending 4 inches and the latter 3 inches below the costal margin. The disease ran a very rapid course, the patient dying within three months from the time the glandular enlargements were first observed.

This case, then, was one of acute lymphatic leukæmia; and in such cases it is not uncommon to find little or no increase in the total number of the white corpuscles, and if this increase does appear it is frequently as one of the terminal events of the disease. There was no gland excised in this patient and a post-mortem examination was not permitted.

ADENITIS OF DOUBTFUL NATURE, WITH MALIGNANT DEVELOPMENTS.

The third case is one of considerable interest, for, to begin with, it was regarded as having the characters of one of the granulomas. Subsequently, however, the glands became overrun with lymphocytes and had therefore the appearances of lymphosarcoma.

CASE 3.—The patient was a man, aged 59, and he was under observation more or less continuously from July 1st to the time of his death on Nov. 10th, 1911. The symptoms began two years previously with a "sore throat and enlarged tonsils." Soon afterwards the glands in the right side of the neck were seen to be enlarged. This swelling gradually increased in size, and about a year later there was enlargement of the glands on the left side of the neck. Later on there were swellings noted in both armpits and in the groins. There seem to have been no constitutional symptoms complained of up to this time, but the patient stated that he had lost 3 stones in weight in the previous three years. Two years before the appearance of the glandular enlargements he contracted syphilis, for which illness he took medicine for a period of two years. Previous to this he had always been a healthy man. His wife and children were alive and well.

On admission to hospital the patient was seen to be a well-built and muscular-looking man. There were no signs of emaciation. There were considerable masses of glands on both sides of the neck, situated chiefly round the angles of the jaw. The individual glands varied a good deal in size and some were larger than a pigeon's egg. There was no definite matting together of the glands, which felt rather elastic to the touch. The right tonsil was of about the size of a walnut, the left of the size of a marble. Both had a pale, gelatinous look, and were tense and elastic on palpation. There were glandular enlargements in both axillæ and in both groins. Neither liver nor spleen was enlarged. The teeth were carious and deficient. There was a faint haze of albumin in the urine. No subcutaneous nodules were to be made out.

A gland was excised from the neck and examined histologically by Professor J. H. Teacher, who reported that the sections had all the appearances of a chronic tuberculous adenitis, with a number of foci of septic softening. A pure culture of staphylococcus albus was obtained from the gland. But in view of the history of syphilis that the patient had given, a Wassermann reaction was sought for and found to be markedly positive. This fact was now laid before Professor Teacher, and he replied that as the appearances of tubercular adenitis are so similar to the chronic adenitis met with in tertiary syphilis, the sections he had examined might quite well come from a glandular enlargement of syphilitic origin.

The patient was therefore given an intravenous injection of salvarsan, and this was repeated a fortnight later. There seemed no doubt whatever that for some days after the first injection there was definite diminution in the size of the enlarged glands, but with the second dose little change was to be noted. Subsequent to this the glands seemed to enlarge again, so that after two months in hospital the glandular condition was practically the same as on admission; the patient had lost 4 lb. in weight, but otherwise his condition seemed little altered. At this time there was no appearance of enlargement of the spleen or liver.

Iodide of potassium was now administered in from 10–20 grains three times a day, and this was continued for the next six weeks. There was, however, no improvement, and by Oct. 11th the glands in the neck, axillæ, and groins were distinctly larger than a month previously. There was now a tumour mass of the size of the closed fist to be made out in the epigastrium and there were also signs of fluid in the left pleural cavity, possibly secondary to some tumour growth in the lung.

A gland was again excised, this time from the axilla, and on examination Professor Teacher reported that it had all the appearances of lymphosarcoma. The gland was overrun with lymphocytes which entirely obscured its fibrous stroma, and the periglandular connective tissue was also infiltrated with lymphoid cells. Cultures were taken from the gland and animals were injected, but with negative results in both cases.

By Oct. 28th the glands in the armpits and in the groins were still larger, as large as a hen's egg, and the tumour mass in the epigastrium could be palpated 2 inches below the umbilicus. The spleen was also greatly enlarged. The patient died about a fortnight later. The blood was examined on two occasions, but showed no very marked abnormality.

Blood Counts in Case 3.

	Red corpuscles.	White corpuscles.	Hæmoglobin.
July 1st, 1911	4,800,000 per c.mm.	9,800 per c.mm.	70 per cent.
Oct 28th, ,,	4,624,000 ,,	11,874 ,,	80 ,,

Differential Counts of White Cells.

	Polynuclears.	Lymphocytes and mononuclears.	Eosinophiles.	Mast cells.
July 17th, 1911	47 per cent.	48 per cent.	3 per cent.	2 per cent.
Oct. 20th, ,,	67 ,,	31 ,,	2 ,,	—

It is most unfortunate that a post-mortem examination was not obtained, as it would have shown what had been the relationship of the primary adenitis to the subsequent lymphosarcomatous growth. But judging from the facts that are before us I am disposed to regard the case as having been, to begin with, either one of tuberculous or of syphilitic adenitis, more probably the latter. Later on the glands apparently took on a lymphosarcomatous growth, but at what stage of the illness this more malignant development appeared it is impossible to be sure.

HODGKIN'S DISEASE.

The fourth case had something of the same clinical features as Case 1, but on histological examination the glands of Case 4 were found to be quite typical of Hodgkin's disease.

CASE 4.—The patient was a schoolboy, aged 11, and he was in my wards from August 4th, 1911, till the time of his death on Nov. 9th. The history of the illness is not very definite, but as far as could be made out there had been some enlarged glands in the neck when the boy was 6 years old. This swelling seems to have disappeared, but to have become noticeable again about a year ago. The boy was taken to the surgical wards in the middle of June (1911) on account of enlarged glands, but subsequent to this they lessened greatly in size, and by the beginning of August the chief complaint was of anæmia, breathlessness on exertion, and swelling of the face and legs.

On admission to the medical wards the skin and mucous membranes were seen to be exceedingly pale, and there was considerable œdema of the face, feet, and legs. No enlarged glands were noted at this time. There were some small

[6] A note of this case was published in THE LANCET of July 18th, 1903, p. 162.

moist râles at both bases and at the left apex, but no enlargement of the liver or spleen. There was a faint trace of albumin in the urine, and the red corpuscles were less than 1,000,000 per c.mm. During August and September there was fairly severe diarrhœa which was difficult to check, and this, along with the râles in the chest, was very suggestive of a widespread tuberculous disease.

During the latter part of September the patient began to improve very greatly and the œdema disappeared. The anæmia, too, became much less marked. Towards the end of September, however, the glands in the neck again began to enlarge, and so rapidly as to suggest a fairly acute inflammatory condition. There was fever, too, of a somewhat irregular type. It was chiefly the glands on the right side of the neck that were enlarged, and they were very soft and elastic to the touch, and freely moveable in their surrounding connective tissue. By the middle of October the œdema of the face and feet returned and the anæmia began to increase again. By this time the glands were lessening in size. One of them was excised, and on examination showed the histological characters of a typical Hodgkin's disease. The boy grew rapidly worse and died on Nov. 9th. The blood was examined on various dates with the following results:—

Blood Counts in Case 4.

	Red corpuscles.	White corpuscles.	Hæmoglobin.
Aug. 4th, 1911...	980,000 per c.mm.	5,600 per c.mm.	18 per cent.
,, 11th, ,, ...	1,140,000 ,,	5,000 ,,	18 ,,
,, 17th, ,, ...	1,100,000 ,,	5,200 ,,	18 ,,
,, 24th, ,, ...	1,080,000 ,,	4,800 ,,	18 ,,
,, 31st, ,, ...	1,130,000 ,,	5,100 ,,	20 ,,
Sept. 20th, ,, ...	2,900,000 ,,	5,800 ,,	40 ,,
Oct. 2nd, ,, ...	3,220,000 ,,	4,900 ,,	38 ,,
,, 19th, ,, ...	2,815,000 ,,	3,500 ,,	30 ,,
,, 30th, ,, ...	1,550,000 ,,	11,800 ,,	20 ,,
Nov. 8th, ,, ...	940,000 ,,	4,400 ,,	13 ,,

Differential Count of White Cells.

	Polynuclears.	Lymphocytes.	Large mononuclears.
Oct. 15th, 1911...	53 per cent.	39 per cent.	8 per cent.

Necropsy.—At the post-mortem examination large glandular masses were found in both sides of the neck, and smaller glands were seen running into the thorax and surrounding the superior vena cava: the œdema of the face was evidently due to pressure on this vessel. The prevertebral glands and the glands at the root of the mesentery were also considerably enlarged. Smaller masses of glands were found in both axillæ. The largest glands came from the neck and were of about the size of a walnut; in consistence they were slightly firmer than a normal gland. The spleen was considerably enlarged and rather fibrous in structure. The marrow in the shaft of the femur was vascular and red. The other organs were very anæmic but otherwise presented little abnormality.

Histological examination of a number of glands showed them all to have the structure of a typical case of Hodgkin's disease.

HODGKIN'S DISEASE: VACCINE TREATMENT.

Case 5 was also one of Hodgkin's disease, and is of interest in that a micro-organism was cultivated from the excised gland and the patient treated by a vaccine prepared from this bacterium.

CASE 5.—The patient was a man, aged 24, and he was admitted to my wards on Sept. 6th, 1909. He remained under treatment for a period of nine months. The beginning of the illness may be dated from April, 1908, when there was noticed for the first time a small lump immediately above the right clavicle. This swelling gradually increased until by the end of August, 1909, there was a considerable tumour mass occupying the right side of the neck. The patient insisted that his general health had all along been excellent; he was always able for any sort of exertion, and his appetite had always been good.

When admitted to hospital in September, 1909, he was seen to be a well-nourished man. There was a considerable swelling on the right side of the neck extending from the mastoid process down to the clavicle. The swelling was apparently made up of a number of enlarged glands, more or less matted together and of firm consistence. On the left side of the neck there was an enlarged gland underneath the upper end of the sterno-mastoid and two enlarged glands immediately above the clavicle. In the right axilla there was a mass of glands nearly as large as a hen's egg; one enlarged gland was to be felt in the left axilla.

There was apparently also some enlargement of the mediastinal glands, for there was an area of dull percussion at the upper end of the sternum, the transverse measurement of this area being 5 inches at the sterno-clavicular articulations and 3½ inches at the level of the fourth costal cartilages. The sternal dulness was continuous below with the upper border of cardiac dulness, and the right border of cardiac dulness extended 1½ inches to the right of the mid-line; the left border was well within the nipple line. There was diminished resonance at the right supraspinous region and in the right infraclavicular area. The breath sound was slightly deficient at the right apex. But there was no dyspnœa, no stridor, and no difficulty in swallowing. The voice, too, was quite clear, and the tonsils were not enlarged. The examination of the abdomen was negative, and in particular the spleen was noted to be of normal size. The inguinal glands were not enlarged.

Glands were excised for diagnostic purposes from the left side of the neck on three different occasions—namely, on Sept. 13th, Oct. 6th, and Feb. 28th—and a subcutaneous nodule from the front of the chest on April 10th.

The histological appearances in all of the glands were much the same. There was hyperplasia of the lymphoid areas and the sinuses were crowded with lymphocytes. Scattered through the sections were small areas of polynuclear leucocytes, and round these were aggregations of small giant cells of the type seen in Hodgkin's disease, many of the cells being very large mononuclear cells and others having several nuclei. Eosinophile cells were present, especially in the neighbourhood of the giant cells. Some of the areas with polynuclear cells were necrotic.

In the gland excised on Feb. 28th there was more connective tissue round the gland and the accumulations of polynuclear cells were larger and had more the appearance of abscess formation. The nodule from the skin showed the same collections of polynuclear leucocytes with the giant cells round about them.

No cultures or smears were made from the gland first excised. But in the smears from the second gland there were found numerous beaded, rod-shaped organisms, and the same bacterium was grown on one of the culture media. In another tube a staphylococcus was obtained, but as this organism was not prominent in the smears it was discarded. No micro-organism was found in smears or in cultures from the third gland or from the nodule excised.

The progress of the case while in hospital was very slow. To begin with, treatment was by liquor arsenicalis (♏ iii.–vii. ter in die), but with little apparent benefit, for by the middle of October the swelling in the neck seemed greater than on admission. Early in November X ray treatment was begun, but again with no very great improvement.

A vaccine was now made by Dr. J. A. Campbell from the diphtheroid-like organism he had grown from the gland excised, and injections were given every ten days during December and January. By Christmas time there was certainly some diminution in the size of the glands, and by the end of February the improvement was very decided. The mediastinal dulness was now little more than normal, though the right border of cardiac dulness extended for over an inch to the right of the mid-line. But in March and April there seemed some recrudescence of the disease in that the glands on the left side of the neck were increasing in size. There appeared about this time on the right front of the chest a number of little subcutaneous nodules which ranged in size from that of a pea to a millet seed. The skin over the nodules was slightly reddened. It was one of these nodules that was excised and examined histologically.

The vaccine treatment was started again on April 18th, and there was again a very great improvement in the patient's condition and a great diminution in the size of the swellings. All the time the patient was in hospital X ray treatment was being persisted with as the state of the skin would permit; but it was during the periods of vaccine treatment that improvement seemed greatest, and this improvement seemed to cease when the injections were intermitted, to begin again with the resumption of the treatment.

The patient's general health all the time he was under observation remained very good. The weight ranged from 9 st. 12 lb. to 10 st. 7½ lb. He sweated, however, profusely, especially at night, and this sweating continued from

September to the end of March. There was some slight fever almost from admission till early in March, the range of temperature being from 97° to 100° and occasionally 101°. Seldom did the temperature remain normal for more than a fortnight at a time; there was, however, no apparent periodicity in the course of the temperature.

There was never any considerable degree of anæmia, the range of the red corpuscles being from 5,470,000 to 4,120,000 per c.mm. and the hæmoglobin from 95 to 78 per cent. From the day of admission onwards till March 15th there was a definite leucocytosis, ranging from 38,200 to 16,000 per c.mm. On April 2nd the white cells fell to 8000 per c.mm., and from that date onwards the range was from 17,800 to 10,000 per c.mm. Some of the counts may be given:—

Differential Counts in Case 5.

	Poly-nuclears.	Lympho-cytes.	Large mono-nuclears.	Eosino-philes.
Sept. 8th, 1909...	84 per cent.	3 per cent.	7 per cent.	6 per cent.
Dec. 25th, ,, ...	78 ,,	...12 ,,	... 2 ,,	... 8 ,,
April 4th, 1910...	72 ,,	...16 ,,	... 1 ,,	...11 ,,
April 24th, ,, ...	76 ,,	...12 ,,	... 5 ,,	... 7 ,,
May 22nd, ,, ...	72 ,,	... 7 ,,	...16 ,,	... 5 ,,

The patient was dismissed from hospital at the end of May, 1910, very greatly improved, the glandular enlargements having almost entirely disappeared, and with instructions to report himself in a few weeks' time. This he unfortunately failed to do, and nothing more definite is known regarding the subsequent history of his illness than that he died in March, 1911.

It is not claimed that the micro-organism grown from the gland in this case is the specific cause of Hodgkin's disease, or even that the vaccine treatment produced the improvements above recorded. One knows how often the glands lessen in size in such cases quite apart from treatment of any sort. Still, the observations are of some interest, and it might be worth while to investigate other cases along similar lines.

ENLARGEMENT OF CERVICAL AND MEDIASTINAL GLANDS (? HODGKIN'S DISEASE).

The next two cases are more difficult to classify. Both may have been suffering from Hodgkin's disease, but of this one cannot be certain.

CASE 6.—The patient was a woman, aged 32, and she was admitted to my wards on Oct. 13th, 1908, remaining under treatment for a period of four months. Her complaint was of swelling of the glands on the right side of the neck and of great shortness of breath.

The illness seemed to date from December, 1907, when the patient first complained of pain in the right shoulder and extending down the arm to the finger-tips. About this time an enlarged gland was noted on the right side of the neck. The pain continued more or less severe for six months, and the swelling in the neck gradually increased in size, some months later the glands on the left side beginning also to enlarge. There seems to have been breathlessness from the beginning of the illness, but at first it was slight and present only on exertion. It gradually became more severe, and subsequent to June, 1908, the patient had not been able to sleep except in a sitting posture. There had been some cough for a week or two before admission to hospital but scarcely any spit. The general health seemed to have been good, and there does not seem to have been much loss of weight.

On admission the patient was seen to be a well-developed and well-nourished woman. Her breathing was noisy and stridulous, and there was a frequent rather brassy cough. She would not lie down in bed as the upright posture was the only one in which she could breathe with any comfort. There were enlarged glands just above the clavicles on both sides of the neck, but they were much larger on the right side than on the left. The mediastinal glands were apparently also enlarged. There was a very dense dull note all over the upper lobe of the right lung, and the same note was obtained over the manubrium sterni. At the left apex there was a comparatively dull note as far down as the second rib. Behind on the right side the dull area extended downwards to near the angle of the scapula. Over both upper lobes the respiratory murmur was distinctly diminished in volume, but over the right it was also high-pitched and had a tubular quality. The heart was normal in size and position. There was no enlargement of the axillary or inguinal glands, and liver and spleen seemed normal in size.

A gland was excised from the neck and examined microscopically. The sections showed the gland embedded in dense connective tissue. The lymphoid tissue in the gland was overrun with polynuclear cells which were rather patchy in their distribution. There was also considerable fibrosis, and many very large clear mononuclear cells. The appearances were suggestive of a later stage of Hodgkin's disease, but not sufficiently distinctive to make one certain of the diagnosis.

The treatment in this case was by means of liquor arsenicalis (♏ ii.–v. ter in die), and X rays applied five days a week to the glands in the neck and over the sternum. In a month's time there was a great improvement in the patient's condition. The breathing was much easier, and unless when the patient was lying down the stridor was quite gone. The glands in the neck were much smaller. There was still dulness, with greatly diminished breath sound, over the right upper lobe in front, but behind the dulness had almost entirely disappeared. The note over the left lung was now clear and the breath sound of good volume. The patient had gained 2 lb. in weight.

Improvement seemed to continue for another month; but then the breathing became more difficult again, though never so bad as on admission. The patient began to lose weight. There was a good deal of cough but very little spit, and no tubercle bacilli in the spit. There was little alteration in the physical signs in the chest.

The patient went home early in February as the skin of the neck and chest was too tender to allow of any more X ray treatment. She died a week or two later.

All the time she was in hospital the temperature was distinctly febrile, being frequently as high as 100° and 101° F. There was a constant leucocytosis, the range being from 17,200 to 30,000 per c.mm. The differential count was as follows:—

Differential Counts in Case 6.

	Poly-nuclears.	Lympho-cytes.	Large mono-nuclears.	Eosino-philes.
Oct. 14th, 1908...	82 per cent.	8 per cent.	7 per cent.	3 per cent.
Dec. 12th, ,, ...	86 ,,	... 5 ,,	... 7 ,,	... 2 ,,

There was no diminution in the number of the red corpuscles.

The condition in this case, then, was apparently one of enlargement of the cervical and mediastinal glands, but what the nature of the enlargement was one cannot be quite certain.

HODGKIN'S DISEASE OR LYMPHOSARCOMA?

CASE 7.—The patient was a young woman, aged 18, and she was under observation and treatment for three months—from Oct. 1st to Dec. 28th, 1907.

The history of the illness was to the effect that about a year before admission to hospital she noticed a swelling just above the right clavicle. Similar swellings appeared higher up in the neck and ultimately coalesced to form the considerable mass noted on admission. There was never any pain in the tumour, and the skin over it was at no time reddened. A fortnight before admission there was some breathlessness and a cough, but no spit. The voice, too, had become husky. There had been no loss of flesh, and the patient was feeling well and taking her food well.

On admission the patient was seen to be well nourished and without any appearance of emaciation. When sitting up, or when lying on the left side, there was little dyspnœa, but when lying on the back or on the right side there was stridulous breathing, suggesting pressure on the trachea. The cough had a brassy quality.

There was a large swelling on the right side of the neck extending from the clavicle up almost to the lobe of the ear, and the larynx and trachea were displaced considerably to the left of the middle line. The tumour mass was hard to the touch and fairly moveable. It seemed to consist of a mass of glands more or less matted together. The glandular enlargement apparently extended some distance into the mediastinum, for there was manubrial dulness with a transverse measurement of 4 inches. At the lower end of the sternum, too, there was a patch of dulness extending 1¼ inches to the right of the middle line, and the heart seemed slightly displaced to the left. The respiratory murmur was equal and vesicular on both sides. The tonsil

were not enlarged, and neither were the axillary, inguinal, or abdominal glands. The spleen extended 1 inch below the costal margin, but the liver was not enlarged.

The patient was treated to begin with with arsenic, and ten days later X ray treatment was commenced. At the end of six weeks a very considerable improvement had taken place in her condition. She had gained 3½ lb. in weight, and the swelling in the neck was considerably less, the circumference of the neck measuring an inch less than formerly. There was still manubrial dulness, but the dyspnœa and stridor had entirely disappeared, and the right border of cardiac dulness was now at the middle line. Six weeks later still the enlarged glands in the neck had almost disappeared, but the manubrial dulness still persisted. The temperature was subnormal throughout the illness. Examination of the blood gave the following results:—

Blood Counts in Case 7.

	Red corpuscles.	White corpuscles.	Hæmoglobin.
Oct. 1st, 1907...	4,800,000 per c.mm.	14,000 per c.mm.	60 per cent.
Nov. 16th, ,, ...	4,000,000 ,,	14,000 ,,	85 ,,
Dec. 28th, ,, ...	4,500,000 ,,	9,800 ,,	78 ,,

Differential Count of White Cells.

Polynuclear cells ...	80·0 per cent.	Large mononuclears	8·5 per cent.
Lymphocytes	10·5 ,,	Eosinophiles	1·0 ,,

The subsequent history, as obtained from an aunt of the patient, was to the effect that about four months after dismissal the glands again enlarged and there was a return of the dyspnœa. The patient went to Ireland and died two years later with a "decline"—that is, about three and a half years from the time the swelling in the neck was first noted.

No histological examination was made in this case, so it is impossible to be certain of the nature of the glandular enlargement: it might have been either Hodgkin's disease or a lymphosarcoma.

ENDOTHELIOMA (?)

The last two cases fall to be grouped with the malignant neoplasms, but the nature of the disease process in both cases was not determined till after death.

CASE 8.—The patient was a man, aged 43, and he was in my wards from July 28th till the time of his death on Nov. 18th, 1911.

The history of the illness is to the effect that three years ago the patient received a blow on the left side of the face and neck. He was not badly hurt, but three days later he noticed some swelling on this side of the neck, and for the next four weeks the swelling gradually increased in size. Plasters were applied and the swelling lessened very much, though it is not certain that it entirely disappeared. A year ago the swelling again became rather prominent, and since then it had gradually increased in size. Six months later the swelling appeared on the right side of the neck, and about this time the patient began to have some difficulty in speaking and swallowing, due, he said, to a lump at the back of his throat. There is no history of much constitutional disturbance or of any notable loss of weight.

On admission to hospital the patient was seen to be a well-developed man but rather emaciated. There was a considerable glandular enlargement on both sides of the neck involving chiefly the glands about the angles of the jaw. The mass on the right side seemed moderately moveable, but that on the left was rather firmly bound down to the underlying structures, and the individual glands seemed somewhat matted together. There was limitation in the movements of the head, not only of rotation, but also of flexion and extension. The jaws, too, could only be separated a short distance, about an inch at the most, and there was thus some difficulty in making a satisfactory examination of the fauces. It was sufficiently evident, however, that there was a large swelling in the posterior wall of the pharynx pushing the soft palate some distance forwards, and it seemed reasonable to suppose that this swelling was continuous with the swellings on both sides of the neck. There was difficulty in protruding the tongue and also in swallowing, but there was no dyspnœa, though the breathing was noisy and the speech indistinct, suggesting some obstruction about the posterior nares. The teeth were in a rather bad condition. There was no pulmonary or cardiac lesion, and no enlargement of the liver or spleen, or of the axillary or inguinal glands.

A gland was excised from the neck and examined by Professor Teacher, who reported that the sections showed a very chronic inflammatory condition, with here and there some aggregations of polynuclear cells. The culture media remained sterile.

In the next four weeks the patient was apparently getting worse. He was losing weight, and there was difficulty in swallowing solids, and considerable respiratory embarrassment. The case clinically had all the features of a malignant growth, and as this had not been confirmed by the histological examination a second gland was excised towards the end of September. Professor Teacher reported that "this gland shows practically the same condition as before—viz., chronic lymphadenitis, with granulation formation, fibrosis, and foci of polymorphonuclear leucocytes."

The administration of fibrolysin was started about the beginning of September and continued for several weeks with apparent relief as regard the symptoms, for by the beginning of October the glands seemed smaller and the dyspnœa was much less. Subsequent to this, however, the glands enlarged again and the patient began to emaciate rather rapidly and to lose strength; he died on Nov. 18th.

During the 16 weeks the patient was in hospital there was some slight fever, the temperature never remaining normal for longer than one week at a time, but it was rarely higher than 100° and only once as high as 101°. The blood count (July 31st, 1911) in this case was as follows: Red corpuscles, 4,410,000 per c.mm.; white corpuscles, 21,250 per c.mm.; hæmoglobin, 74 per cent.

The leucocytosis persisted all the time he was under observation, never being less than 14,200 per c.mm. The differential count on July 31st gave the following proportions:—

Polynuclear cells ...	81 per cent.	Large mononuclears...	10 per cent.
Lymphocytes	8 ,,	Eosinophiles	1 ,,

Necropsy.—At the post-mortem examination there was noted to be an enormous collar of glands in the neck extending from the ears to the clavicles. The glands were firmly matted together. The pharynx was pushed forwards, it and the œsophagus being compressed by the growth, though there was no infiltration of their walls. There was no extension of the growth into the nose or ethmoid cells, but there was some erosion of the bones forming the base of the skull. Neither the tonsils nor the bronchial glands were enlarged, and there were only a few slightly enlarged glands in the upper part of the thorax. There were no metastases to be found.

A somewhat detailed examination of the tumour was undertaken by Dr. J. H. McNicol, and his preparations have been submitted to Professor Teacher, who, after examining a considerable number of slides taken from different portions of the growth, is of opinion that the neoplasm is probably of the nature of an endothelioma. Whether this is a primary growth in the glands or secondary to growth elsewhere one cannot be certain, but careful search has failed to discover a primary seat of origin either in the carotid body or on any endothelial surface. If this growth is an endothelioma it differs in certain essentials from the cases of endothelioma of the neck described by Gilford,[7] in which the lymphatic glands do not seem to have been implicated in any way whatever.

SARCOMA.

CASE 9.[8]—The patient was a man, aged 38, and it was in August, 1905, that he first noted a swelling at the angle of the right jaw. This swelling gradually increased in size and other little tumours appeared in its neighbourhood. By the end of December (1905) enlarged glands were also noted on the left side of the neck. He was admitted to hospital in February, 1906, and then it was observed that on the right side there were enlarged glands extending from the mastoid process to the clavicle and varying in size from that of a pea to that of a walnut. On the left side there was one large gland, the others being small like peas. Some of the glands felt very hard and others rather elastic, but they were all freely moveable. Neither the axillary nor the inguinal glands were enlarged, and the liver and spleen were normal in size. Examination of the blood showed no abnormality.

The case was thought to be one of Hodgkin's disease and was treated with arsenic. There was at first great

[7] Practitioner, December, 1904, p. 729.

[8] This case was published in THE LANCET of July 11th, 1908.

diminution in the size of the glands, but subsequently they again enlarged, and by August, 1906, they were as large as ever they had been. There was now noted a swelling of the size of a marble in the roof of the mouth, and some weeks later subcutaneous nodules over the right pectoral region. Towards the end of September the breathing became noisy, with spasms of dyspnœa, and the patient died early in October. There was no anæmia in this case and no leucocytosis; the proportion of polynuclear cells was 81 per cent., of mononuclears 18 per cent.

Necropsy.—At the post-mortem examination a large tumour mass was found surrounding the larynx, trachea, and œsophagus, and extending upwards through the base of the skull and forwards into the roof of the mouth. This growth was found to be a round-cell sarcoma, and the nodules in the pectoral region had the same structure. It was impossible to determine the point of origin of the primary growth, or that the glandular enlargement was not from the first sarcomatous in origin, for microscopic examination failed to give evidence of there having been any previous lesion in the glands affected.

In concluding, I wish to express my great indebtedness to my colleagues at the Royal Infirmary for their able assistance in investigating the above cases—to Mr. Paterson, who excised the glands in the various cases; to Professor Teacher for the histological examination of the glands; to Dr. Campbell for the bacteriological examination; and to Dr. McNicol for his study of Cases 4 and 8. Without the aid of all these gentlemen the records of the cases would have been very incomplete.

A Lecture

ON

AMPUTATION FOR DIABETIC GANGRENE.

Delivered at St. Bartholomew's Hospital on Dec. 13th, 1911,

BY C. B. LOCKWOOD, F.R.C.S. ENG.,

SURGEON TO THE HOSPITAL.

GENTLEMEN,—I lecture to-day upon a most dangerous complication of a most dangerous disease—diabetic gangrene.

PRELIMINARY REMARKS.

The word diabetes does not in itself afford much information. It means "the passer through" or syphon, and one of the patients about whom I am going to speak certainly was "a passer through." In these vessels Mr. Grange has put the quantity of urine passed in 24 hours, and it amounts to one and a quarter gallons; sometimes it was at least one and a half gallons.

Glycosuria and its Results.

This urine was of high specific gravity, because it contained a huge quantity of grape-sugar or dextrose. In this large basin Mr. Grange has kindly put the quantity of dextrose which was contained each day in the urine. That basin full of sweet substance has in it 13½ ounces. I cannot help thinking that a human being who is passing out one and a half gallons of urine in a day, even if he drinks over a gallon, as this man did, must be draining his tissues of fluid, and no wonder he is thirsty. And if instead of using the sugar for the nutrition of the tissues it is passing out, those tissues will be starved and weight will be lost. Doubtless the blood and the tissues have in them quantities of sugar. Sugar passing through the vessels is likely to damage them; presently I will tell you about the condition of the arteries. But more than that, the sugar passing along the vessels and into the tissues makes them more susceptible to septic infection. A broth or gelatin culture with sugar in it is an extra good soil to grow bacteria upon.

Lack of Oxygen.

There is one other point which has struck me very much about the patients who have been operated upon for diabetic gangrene—that many of them were exceedingly blue. Here is an admirable book written by Dr. Langdon Brown, entitled "Physiological Principles in Treatment." I observe on almost every page written about diabetes some reference to the "lack of oxygen," to the "deficiency of oxygen," to the "want of oxygen.' This lack of oxygen plays a very profound part in the causation of diabetic gangrene. Presently you see that the want of oxygen is not only general, as may be betokened by the blue lips, the purple face, and the blue extremities, but is also local, for there is a local asphyxia of the tissues which may end in them dying. In diabetic gangrene the peripheral conditions favour the death of the tissues. They are blue, ill-supplied with oxygen, and saturated with sugar.

Calcareous Condition of Arteries.

But in addition the arteries are oftentimes inflamed or calcified and ill-suited for the circulation of the blood.

Here are some calcified arteries from the museum. It might be thought that they are exaggerated specimens of calcified arteries, but one of the patients for whom I performed amputation of the leg for diabetic gangrene had arteries which were so calcified that Mr. H. R. Wadd aptly compared them to a bird's trachea. Another patient with diabetic gangrene had arteries which were so brittle and calcified that they would not tie, and in the end the vessel was secured by passing a piece of silk underneath it and the surrounding tissues, and then tying it with extreme caution. And in these cases of gangrene the calcareous vessels can be seen in an X ray photograph, as in a patient who was in the casualty ward with gangrene of his leg.

Albuminuria.—Neuritis.

Many with diabetes who have reached the stage of gangrene have also albumin in the urine, and in the notes you will frequently find that the urine contained sugar in quantities and also albumin. Albumin may mean little or it may mean much, but it will tell you this: a patient with sugar and with albumin in his urine is of necessity in greater danger than is one with sugar alone. When the urine has renal casts in it the kidneys are gravely and permanently diseased and may not continue to function. Some who are supposed to die from diabetic coma may have died with uræmic poisoning. Lastly, in diabetic gangrene the peripheral nerves are in an unsatisfactory state, probably before the gangrene supervenes. But if the gangrene has supervened the neuritis is intense, and those with diabetic gangrene suffer the most horrible anguish; a very good reason why they should have prompt surgical help.

A Case of Diabetes following Cholangitis.

CASE 1.—As bearing on the causation of diabetes. A patient had an acute septic inflammation of the gall-bladder, which was drained. Then the liver became swollen and tender, and the gall-ducts were probably inflamed. During the course of the cholangitis the pancreas became inflamed. The stools were full of fat and starches, and at the same time there were obvious swelling and tenderness in the region of the pancreas. The patient must have had great tenacity of life, because she recovered from these conditions. There is one point which I will mention now, because it may be of service: it is that her recovery began after she was dosed with urotropine. I think that is a drug which is not only excreted by the kidneys, but also by other glands and by the pancreas. So urotropine was given, and whether by chance or not she certainly began to improve. But then it was discovered that the urine contained sugar in considerable quantities.

Site of Gangrene.

Towards the end of diabetes a time arrives when the tissues which are in the condition that I have described may die. The gangrene most often takes place in the lower extremities. But one of my patients with gangrene of the leg also had patches of gangrene on the back. Another had a patch of gangrene upon the thumb. It is possible that so-called spontaneous gangrene of the penis and scrotum is allied to diabetic gangrene. You may not have heard of spontaneous gangrene of the penis and scrotum, but every now and then a patient is brought into the surgery whose penis and scrotum have become black and gangrenous, without obvious cause.

AMPUTATIONS.

Amputations for diabetic gangrene are not very common. But out of 54 major amputations—interscapulo-thoracic,

shoulder, hip, thigh, leg—16 were operated upon for gangrene, and of those half were operated upon for diabetic gangrene. The mortality in these eight was very high indeed. Five had amputation performed at the junction of the upper and middle third of the leg for diabetic gangrene, and only one of them is known to have survived. It is possible that another survived, but it is not in my notes; and we are safe in assuming that four out of five succumbed. The patient who did not die had not got diseased arteries. The urine contained 4 per cent. of sugar at times and a moderate quantity of albumin.

Three patients had amputation performed through the thigh for diabetic gangrene. One of these died, but two recovered. The one who died had exceedingly calcareous arteries, a very unfavourable complication.

Causes of Death after Amputation.

Death after amputation is brought about either by septic infection or diabetic coma. The flaps have, not infrequently, sloughed, and the stump has become profoundly septic. Diabetic coma may follow the sepsis or come on by itself. The patient, after smelling of acetone, becomes apathetic, then drowsy, comatose, stertorous, and at last dies. You are familiar with the smell of acetone, for acetone collodion is frequently used. Once familiar with the smell it is easily detected, and is a profoundly unfavourable sign—the precursor of diabetic coma.

Shock.

A patient may have those curious black asphyxiated patches about the foot, and yet they may not become gangrenous. Inky black they may exist for weeks or months, but the onset of sepsis is most serious and dangerous. The sepsis may be brought about by some trivial cause.

CASE 2.—For instance, a lady who had 4 per cent. of sugar in the urine applied strong sulphuric acid to a corn upon the little toe, and that resulted in a small septic wound. From that the diabetic tissues became infected, the infection spread up the leg, and amputation was performed. She died from shock through loss of blood. The femoral artery was held by the fingers, the fingers did not control it properly, and there was considerable loss of blood, from the shock of which she never recovered. Shock is one of the dangers of operations for diabetic gangrene.

Septic Infection.

In another case the onset of diabetic gangrene was due to suppuration beneath a corn. I can recall another in which the diabetic gangrene was caused by a tack which ran into the foot whilst the patient was walking about without shoes or stockings on. When once septic infection has started it spreads with great rapidity. The foot becomes red and œdematous, and the sepsis spreads up the lymphatics and up the tendon sheaths. The last might not be noticed because the tendon sheaths are beneath the deep fascia, so that the inflammation may have spread high without being seen. This has a practical bearing when we have to decide where to amputate. If the seat of election be infected tissues the sepsis continues in the stump, and the patient is in horrible danger of gangrene of the flaps and of acetonæmia and diabetic coma. The infection occasionally spreads by way of the veins, for clots form in them, and these are, of course, infected.

Notes of Case of Amputation.

CASE 3.—Some time ago a patient, aged 65, after having had diabetes for several years, got gangrene of the toes. In addition to the gangrene there were inflammatory œdema of the dorsum of the foot and deep-seated tenderness in the leg. This was suspected to be due to sepsis passing up the deeper tissues, especially the sheaths of the tendons. He was profoundly ill. Owing to septic absorption the pulse was at least 125 and intermitted.

Intermittent pulses are to be studied. We often have patients in the wards whose pulses are beating quickly and intermit, and you will have to be able to form an estimate of what that intermittency means. If the patient has obvious mitral or aortic disease, an intermittent pulse is a serious matter. If a patient has an intermittent pulse which, when a strain is put upon the heart, intermits more, that is serious. But if a patient has a pulse which intermits, and becomes steady when a strain is put upon the heart, clearly that is not important. A patient in the ward the other day had a large cystic adenoma of the thyroid gland; the pulse was rapid and intermittent. It was of importance, in view of such a grave operation, to know what would happen to the heart during the performance of the operation. So she was made to get up and walk about the ward, and we found her heart became steadier. A little boy had acute appendicitis; he was a delicate little creature, and his pulse intermitted. He was sat up in bed, and walked about the room, and then the pulse became steady.

So the intermittent pulse of this old man had to be taken very much into account. He was taking alcohol and continued it. And in addition he was dosed with strophanthus. This is a drug which makes the ventricles of the heart beat more strongly, and, of course, strophanthus has an advantage over another drug which is used for the same purpose—digitalis—that it does not contract the peripheral vessels. It would not be rational medicine to give a person with gangrene of the leg a drug which contracted the peripheral vessels and impeded the peripheral circulation. There was one other point in the preliminary treatment. I have told you what a danger the formation of acetone is. The formation of acetone is preceded by the formation of diacetic acid, and therefore considerable doses of bicarbonate of soda were given, at least half an ounce in the 24 hours.

As soon as possible after this preliminary treatment the patient's thigh was amputated. Why should one who has a foot which is gangrenous and dead keep the limb? It is a source of great danger and the toxins absorbed from it add to the dangers of acetonæmia and diabetic coma. In this case no X ray photographs were taken, but the peripheral arteries were not calcareous. The femoral artery, although thickened and chronically inflamed, was not calcareous. But here comes the application of some of the things that I have told you about. We amputated in the way in which I am now accustomed to amputate. We did not apply a tourniquet, Esmarch's or otherwise, to the thigh. Think of applying a band of that sort to one of those calcareous arteries! No wonder after the use of Esmarch's bandages and bands gangrene recurs in the flaps. But tourniquets, besides crushing these arteries, are very apt to press and injure the vein which runs at the side of the artery. Again an elastic tourniquet, besides asphyxiating the whole limb, causes arterial paralysis. When Esmarch's bandage has been used blood goes on dripping from the muscles and flaps, and much valuable time has to be spent in putting on ligatures, when after all it was better that the patient should be back in bed.

Operation.—For this operation the patient was laid on his back on a table and an incision was made at the lower end of Hunter's canal. The superficial femoral artery and vein were then and there secured. When you think about it, the main arteries in an amputation have to be secured at some time or another, and why the surgeon should not begin by securing the great vessels and be finished with them I am at a loss to imagine. There was one little complication in the ligature of these vessels. The superficial femoral artery and vein were so fastened together by inflammation that I thought it better not to waste time in trying to separate them, but tied them together with ordinary chromicised gut ligature. The next step after securing the great vessels was to leave the patient in the same position, and with a scalpel to cut flaps quietly and slowly, and secure each vessel the moment it bled, as in other operations; then to saw through the bone and put the drainage-tube in, and finish the amputation in the usual manner.

Everyone is prejudiced about his own ideas, so I asked Mr. Richard Gill, who gave the anæsthetic, what he thought about the shock in this case, and Mr. Gill was very emphatically of opinion—perhaps he was kind in saying so—that there was none at all—but certainly there was singularly little shock.

This patient, after the operation, was put back in bed. And observe what a parlous condition he was in. He had a pulse which was very rapid for an old man or for anybody else; he had a very high temperature; he had 4 per cent. of sugar in his urine; so acetonæmia was impending. He had some patches which were very blue in colour on the other foot and on the thumb. Of course, the treatment which he had had before the operation was continued—the bicarbonate of soda, the alcohol, and the strophanthus. But now he had a treatment which

surely must be of great importance in these cases. The moment the operation was over we began the continuous administration of oxygen. He had oxygen to inhale for nearly a fortnight. He liked it very much indeed and was pleased to have it; asked for it, and it obviously did immense good.

Remarkable Effects of Oxygen Inhalation.

Do you remember what I said about Dr. Langdon Brown saying in his book on nearly every page relating to diabetes something about the want of oxygen in the tissues and the need for oxygen? And yet it seems strange to me that at the end of that chapter he does not say, "Therefore you must give these patients as much oxygen as you can get them to take."

The administration of oxygen has a most extraordinary effect. I was about to amputate the breast of a stout female whose face and lips were blue. Although most unfavourable, yet it was not right to leave her to die of carcinoma of the breast, which was on the point of ulceration. So before the operation oxygen was ordered to be ready. During the operation the blood which flowed from the wound was deep purple. Then the oxygen was turned on, and at that moment all the wound became vivid red. The blood became arterial instead of being of the colour of dark treacle. That experience has made a most profound impression on my mind. If the tissues are in a condition such as that in diabetic gangrene, perhaps livid, with those dark patches on the heels and back, surely the more oxygen given to those defective tissues the better. I cannot help associating the recovery of that old man with this supply of oxygen, and I should say that the stump did unusually well; it healed by first intention, and the patient lived for 16 months.

Another Illustrative Case.

I will briefly refer to another case which was treated in the same manner. Many of you might have seen the operation performed.

CASE 4.—The patient was in Paget ward. He was certainly in a parlous state. There was extensive gangrene of the left foot and leg. One gallon of urine was passing out of him every day, and it contained 13½ ounces of sugar. He was not very thirsty, although he sometimes drank a gallon of fluid a day. At the time of the operation the pulse was accelerated to 104, and the temperature had been nearly 102° F. The respirations, too, were accelerated, being 24 before the operation. His thigh was amputated in the same way as the last. The main vessels were tied and the bleeding stopped; he was never moved about on the table; and the moment he returned to the ward the continuous inhalation of oxygen was begun. He was very apathetic and sleepy, and was obviously on the verge of acetone poisoning. The urine contained diacetic acid, so that everything was in readiness for acetonæmia, but he survived and improved. For some inscrutable reason the house surgeon in charge of the case stopped the oxygen; perhaps he thought a hospital which was running into debt had no right to spend money on oxygen. But when the oxygen was stopped the patient became worse and I thought he would die. It was begun again and the patient improved, and slowly mended until we were able to send him out of the hospital. His wound, I thought, did remarkably well. Except for the places where the drainage-tube was put in, it healed by first intention, but the drainage opening shortly closed, and he did exceedingly well for such a class of case.

Site of Amputation.

But observe I amputated through the thigh. And I have told you of five cases in which I amputated through the leg, and three or four of them died. I have not time now to go into the reasons of their deaths. One died from shock and hæmorrhage due to the operation, one died from diabetic coma, and one died probably from sepsis.

The dangers of dying from sepsis seem to me far greater if you amputate through the leg, because you have still to deal there with calcareous vessels, and there may be still some infection of the lymphatics, veins, or tendon sheaths. I have clearly made up my mind now, from my limited experience of diabetic gangrene, that the amputation is better performed through the thigh and in the way I have described to you, and better performed at the earliest possible stage of the disease. Do not wait until the gangrene has spread, until the patient has become septic, and until the chances of prolonging life are vastly diminished.

THE TREATMENT OF PUERPERAL SEPTICÆMIA BY BACTERIAL VACCINES.[1]

BY G. T. WESTERN, M.D. CANTAB.,
SENIOR ASSISTANT IN THE INOCULATION DEPARTMENT, LONDON HOSPITAL.

(*From the Inoculation Department, Bacteriological Laboratory, London Hospital—Dr. W. Bulloch.*)

IN the course of a discussion on "vaccine-therapy" held by the Hunterian Society in the spring of 1910 I made a preliminary report on a series of 20 cases of puerperal sepsis which had been investigated in the bacteriological laboratory of the London Hospital. Of these 20 cases 13 had been treated by inoculation. Since then we have continued working on the same lines, with the result that we have now a series of 100 cases which have been investigated, and 56 of these have been treated with vaccines.

The cases in the present series have, with few exceptions, been patients admitted to the puerperal septicæmia ward at the London Hospital. These patients are drawn from the neighbouring districts after confinements in their own homes, often under the most unfavourable sanitary conditions. In many cases they have been attended by a midwife and in others by a private doctor. It will be realised, therefore, that the present series includes only those cases which are looked upon prognostically as of such gravity as to necessitate removal to hospital. It should be added that these cases are all notified under the Act.

As I pointed out in my previous report, the very wide difference in mortality given by different authorities indicates that there is a considerable difference of opinion as to what should be included in the term "puerperal septicæmia." Clinically, a diagnosis of septicæmia rests largely on the temperature, the pulse, or a combination of temperature and pulse. Bacteriologically, a diagnosis of septicæmia may be made on a positive blood culture. If the result of blood culture is negative it does not follow that the case is not a septicæmia. It is well known that a blood culture may be done on one and the same case on several occasions, and be positive one time and negative another time. Further, if several tubes of media be inoculated at the same time some may show growth while others remain sterile. Again, special precautions with regard to media or quantity and dilution of blood may give a positive culture in a case which has been negatived by ordinary routine methods.

I would suggest that the explanation of these facts is that a septicæmia is not in most cases a condition in which multiplication of bacteria takes place to any great extent in the blood stream, but rather a condition in which there is a local bacterial infection around which the tissues have not reacted to form a localising barrier, and, consequently, bacteria are more or less continually being carried away into the general circulation. Here they probably do not survive very long unless they form an embolus or get caught in a thrombus, in which cases pyæmic abscesses may occur. If this is so we have included under the clinical term "puerperal fever" at least two different conditions: (1) a localised bacterial infection in the genital tract which is associated with more or less toxæmia; and (2) a local infection in the genital tract from which bacteria are being carried into the blood stream, continuously or discontinuously. These latter cases constitute the group of true septicæmias, but it must be realised that the two groups merge into one another and clinically cannot always be separated, and this doubtless explains the extraordinary variations of opinion as to the mortality. The determining factors would appear to be the relative balance between the virulence of the infecting agent on the one hand and the resistance of the tissues on the other.

In tabulating the cases which we have investigated and treated an attempt has been made to record those points which are of especial interest without making the tables too full of detail to be easily read. Further, the order in which the cases have been placed has been chosen as far as possible to simplify the deduction of conclusions. The cases are divided into two tables: (1) cases treated by vaccines; and (2) cases untreated by vaccines. In each table the patients

[1] A paper read before the Obstetrical and Gynæcological Section of the Royal Society of Medicine on Feb. 1st, 1912.

who lived are grouped together, as also are those who died. Further, in each of these groups the cases in which there was definite bacteriological evidence of a blood infection are placed first.

I propose now to discuss briefly the results detailed in these tables, and at the same time a few words of explanation will be necessary about some of the headings.

"*Nature of labour.*"—This information is, of course, obtained second-hand, and it will be seen that in many cases, although it is put down as "normal," reference to the column "Other treatment" will show that in reality it was abnormal in so far as there was incomplete delivery of the placenta or membranes.

Out of the 100 cases 25 followed on miscarriage. In only 2 of these was a history obtained of criminal interference. The number of primiparæ, 27—that is, 36 per cent. if we exclude the miscarriages, or 27 per cent. including them—does not appear to be excessive, but in all probability this note is omitted in several more cases.

I regret that I have been unable to obtain more precise details as to examination or interference during the various stages of labour. It would appear, however, from the number of cases in which the third stage was abnormal or incomplete, that the risk of infection in such cases is many times greater than in those where there is interference in the second stage, the reason obviously being that in the third stage there is a wound area exposed, while in the second stage manipulation takes place within the membranes.

"*Day of onset.*"—This is taken as the day on which marked pyrexia was first observed. This is noted in 81 cases. It will be seen that 62 per cent. of the cases occur on the second or third day after delivery. It is also interesting to note that if we take the fatal cases alone the incidence on the second day is as great as that on the third day (11 to 11), while if we take the cases which lived the incidence on the third day is nearly double that on the second day (18 to 10). This suggests that the more virulent the infection the more rapid will be the onset and the more fatal the result.

"*Rigors.*"—It does not appear that any absolute prognostic significance can be attached to the presence or absence of rigors alone. Some of the most virulent and rapidly fatal cases never have a rigor at all, while others may have rigors almost daily for many weeks and eventually recover completely. It has been suggested by Schottmüller that a rigor is indicative of bacteria being thrown into the blood stream, and, further, that the height of temperature is proportionate to the number of bacteria in the blood stream. This is supported by the fact that a single rigor frequently occurs shortly after the operation for clearing out an infected uterus, at which time it is easily conceivable that a few bacteria are shot into the circulation. This is also in accordance with the fact that a blood culture may sometimes show a growth if taken during or soon after a rigor, although previous cultures have remained sterile. It would seem probable, therefore, that the presence of repeated rigors denotes an improperly localised focus of infection, often septic thrombosed veins, which is the basis of a septicæmia.

"*Blood cultures.*"—This has been done in almost every case. 8–10 c.c. of blood is obtained by venipuncture and inoculated into tubes of ordinary glycerine and glucose broth. These are incubated at 37·6° C. for four days before being reported as negative. Some of the more recent cases have been incubated under anaerobic as well as aerobic conditions.

In 96 cases in which the blood has been examined a positive result has been obtained in 39—i.e., 40 per cent. This is clearly an under estimate of the number of true blood infections, as it will be seen that the blood examination has on several occasions been reported negative where pyæmic abscesses afford definite evidence of a blood infection. If it were possible always to take cultures during a rigor or when the temperature was at its highest point, the chances of getting a positive culture would probably be greatly increased. Of the 39 positive results 36 contained streptococci, and of these all but 2 were grown aerobically. Two cases grew staphylococcus aureus and one case grew a Gram-negative coccus which failed to grow in subculture. The two staphylococcus aureus cases were both following abortion, in one instance criminally induced.

"*Uterus cultures.*"—These have been taken by a method similar to one which has been used by Menge and Krönig. This is usually done in conjunction with the operation for removing retained secundines. After the vagina has been thoroughly douched the cervix is drawn down towards the vulva. This tends to straighten any flexion of the body on the cervix. A straight glass tube with a rubber diaphragm at the top is then passed up to the fundus. Having felt that its end is against the fundus it is withdrawn one inch. Knowing, then, that we have that much space to spare we can boldly pierce the rubber membrane with a Pasteur pipette without fear of wounding the wall of the uterus. Material is then sucked into the pipette by means of a rubber teat, and on withdrawing it the tip is sealed in a flame. The material obtained is then examined by films and cultures. On withdrawing the tube the uterus may be cleared out as usual.

As a further safeguard against contamination from the cervix a wider bore tube may first be passed up the cervix for two inches; the rubber capped tube is then passed without touching the cervix at all. It is important that the finger be not introduced before the cultures are taken, as by so doing contaminations may be introduced and also frequently such free hæmorrhage is set up that the specimen obtained contains little more than pure blood.

Cultures were taken from the uterus in 43 cases in this series. In 31 instances streptococci were grown in pure culture. Twice streptococci grew in large numbers, together with a few colonies of coliform bacilli, which were no doubt contaminations from the vagina or cervix. On one occasion staphylococcus albus alone grew, and on one occasion the cultures were noted contaminated. In only 7 cases were the results completely negative, and there is reason to believe that in some instances this was due to faulty technique. It will be seen, therefore, that streptococci occurred in 80 per cent. of the cases examined and in 76 per cent. in pure culture.

It should be remembered that these cases have been investigated entirely with a view to possible specific treatment and not as part of a research into the bacteriology of the genital canal in puerperal fever.

I find that two papers dealing at length with this subject have been read before this section during the last few years. It will therefore be of interest briefly to compare my results with those obtained by the authors of those papers. I refer to a paper by Mr. A. G. R. Foulerton and Dr. W. F. Victor Bonney[2] in 1905 on "The Causation of Puerperal Infections," and one by Dr. A. W. W. Lea and Dr. E. J. Sidebotham[3] in 1909 on "The Bacteria of the Puerperal Uterus." It will be remembered that these workers each employed a different technique and obtained widely divergent results. Foulerton and Bonney used a glass tube with a paraffined wool cap at one end. Within the tube was a copper wire bearing a sterile swab. The tube was passed through the cervical canal, and the paraffined cap pulled off by means of a string. The wire with the swab attached to it was then advanced to the fundus and withdrawn again into the tube. The apparatus was then removed, with the swab inside, and plugged at each end. Lea and Sidebotham used a glass tube which was passed up to the fundus, suction being then applied by means of a syringe. It appears to me that the former technique is good, while the latter could not be expected to give reliable results. Turning to their results, briefly, Foulerton and Bonney found that (1) in 12 cases of normal puerperium examined, 100 per cent. sterile; (2) in 40 cases of severe puerperal infection examined, 80 per cent. had bacteria present; and (3) in these 40 cases streptococci or Gram + diplococci were present in 77·5 per cent. On the other hand, Lea and Sidebotham examined the contents of the uterus in 58 cases of normal puerperium and found bacteria present in 80 per cent. In these 46 cases 120 bacteria were found, an average of 2·8 varieties per case. If we compare this with the 100 per cent. sterile results quoted above it appears to me that imperfect technique is the only possible explanation of the difference. The point is important for this reason. If the uterus normally contains numerous bacteria during the puerperium it is clearly futile to waste time isolating pathogenic from non-pathogenic bacteria for the purpose of making a vaccine to

[2] THE LANCET, Jan. 21st, 1905, p. 162. Trans. Obstet. Soc., Lond., vol. xlvii., p. 11.
[3] Proc. Roy. Soc. Med., Obstet. Section, 1909, vol. ii., p. 127.

treat a severe septicæmia. Our results which I have already quoted show that we can obtain a pure culture from the puerperal uterus in 76 per cent. of infected cases. This appears to me to be strong evidence against the correctness of Lea and Sidebotham's results.

It may sound paradoxical, but every bacteriologist will agree that while it is impossible to get a pure primary culture of one organism in 76 per cent. of cases if in reality a mixture is present in the material planted out, imperfect technique is all that is required to enable a mixture of bacteria to grow when in reality only one is present in the material we are intending to examine. I would submit, therefore, that if it is possible to grow a pure culture of one organism from the uterus (which is normally sterile) in 76 per cent. of morbid cases, we have strong evidence that this is really the infecting agent.

Before leaving this section of my paper it is interesting to note that Foulerton and Bonney's 77·5 per cent. of Gram + streptococci and diplococci very closely coincides with our 80 per cent., although they do not appear to have obtained pure cultures in so many cases.

"*Vaccines.*"—Under this heading is indicated whether the case was treated with an autogenous vaccine or whether a "stock" was used—i.e., a vaccine prepared from a culture obtained from another patient. I have wherever possible used an autogenous vaccine. Only where no culture has been obtainable, or where the preparation of an autogenous vaccine is not yet complete, have "stock" vaccines been used. Some cases which have been commenced on a "stock" vaccine, and shown no improvement after several injections, have then been given an autogenous vaccine and have at once responded by a marked fall in temperature and general improvement. I consider, therefore, that an endeavour should be made to obtain an autogenous vaccine from the first in all cases and no valuable time be lost in extensive trials of "stock" vaccines.

With regard to the source from which the vaccine should be made, theoretically an organism obtained from the blood stream is more certain to be the offender than one obtained from the uterus, which is, of course, open more to contaminations. Practically, however, there are some very real advantages in the latter source. Firstly, our figures show a negative result in 60 per cent. of blood culture taken, whereas cultures taken from the uterus are found to give negative results in only about 20 per cent. of cases, and even this could doubtless be reduced if these cultures were always taken by or under the direction of one accustomed to the technique. Secondly, a proportion of blood cultures shows no growth until after two or more days have elapsed. Cultures from the uterus, on the other hand, almost invariably show growth within 24 hours if they are going to grow at all. Further, as the tables show, we can get pure cultures fr om the uterus in 76 per cent. of cases examined, so that in this percentage a vaccine can be prepared within 24 hours of taking our cultures. This is seldom possible from blood cultures, as in them it is only very exceptionally possible to make up a vaccine from the primary culture. I would urge, therefore, that if a case is at all serious, and the uterus is being explored, the opportunity of taking cultures at the same time by some reliable method should never be missed as this may afterwards be an irretrievable loss.

"*Other treatment.*"—Under this heading falls operative interference for the removal of secundines, evacuating pus, &c.; also the administration of antistreptococcus serum. This latter has been given in 18 cases, sometimes in conjunction with and sometimes without vaccines. Of these 18 cases, 7 patients lived and 11 died. We have not noted any cases where antistreptococcus serum appeared by itself to have any marked effect in lowering the temperature or improving the general condition. On the other hand, in one case we have seen antistreptococcus serum given in 20 c.c. doses and repeated for eight doses, and after almost every dose the temperature rapidly ran up from two to three degrees Fahrenheit. This patient eventually recovered after the injections were discontinued. This case very strongly suggested that there was in the serum a distinct toxic element.

"*Results.*"—It is difficult or perhaps even impossible to estimate accurately the benefit derived from any special line of treatment without having for comparison a sufficient number of control cases. These are not at present available.

The present arrangement of the septicæmia ward in this hospital did not exist previously to the commencement of this series of cases, so that it is not possible to obtain a control series from that source.

The 44 cases in this series which have not been treated by vaccines cannot, without reserve, be taken as controls, as they include many mild cases which were not treated because it was considered that they would do well without. In cases where an autogenous vaccine had been prepared it was withheld if the temperature was already falling. Further, as was pointed out by the British Medical Association Committee appointed in 1905 to consider the question of puerperal morbidity, an efficient comparison of the statistics from various hospitals is impossible owing to diversity of standards of morbidity. The standard suggested by that committee includes all cases where the temperature reaches 100° F. on any two of the bi-daily readings from the first to the eighth day after delivery.

Whitridge Williams in a series of 92 cases of puerperal infection had a mortality of 15 per cent., but, as he adds, "our favourable results are probably attributed to the fact that many mild cases are included in our series which would have escaped detection except for the bacteriological examination of the lochia of all febrile cases"; and again, "In my practice such a procedure forms a part of the routine examination in every case presenting a rise of temperature above 101° F."

Perhaps some idea of the type of case we have been dealing with can be gathered from the temperatures. It is, of course, not practicable to show the charts of 100 cases. I have therefore grouped them according to their maximum temperatures, taking the maximum as the highest temperatures which have been reached apart from single rigors.

	Degrees Fahrenheit.	Per cent.
Maximum temperatures	107–108	2·6
" "	106–107	6·6
" "	105–106	32·0
" "	104–105	28·0
" "	103–104	22·6
" "	102–103	6·6

Of the cases with a maximum temperature of between 102° and 103° only one was considered sufficiently grave to require vaccine treatment.

By the courtesy of Dr. Arthur Newsholme I have obtained from the Local Government Board the returns of the last few years of the notified cases of puerperal fever for some 250 odd boroughs and urban districts having a total population of about 19½ millions of people. Calculating from these the mortality per million living, I have compared the figures so obtained with the death-rate from puerperal septic diseases per million living for the whole of England and Wales, obtained from the report of the Registrar-General. From this I find that the mortality of notified cases varies between 57 and 62 per cent. (see Table III.).

TABLE III.

Year.	Boroughs and urban districts.	Population (1901).	Cases of puerperal fever notified.	Cases notified per million living (1901).	Deaths from puerperal septic diseases per million living. England & Wales.	Per-centage mortality amongst notified cases.
1906	258	19,437,867	1467	75·0	47	62·6
1907	257	19,432,397	1394	71·7	41	57·0
1908	259	19,458,754	1323	67·9	39	57·4
1909	258	19,432,190	1357	69·0	40	57·9
1910	253	19,532,548	1340	68·0	—	—

These figures coincide very closely with those published by Dr. Amand Routh in his presidential address to this section last October.[4] Taking the notified cases of puerperal fever and the deaths from puerperal septic diseases in the Administrative County of London during the years 1906–1910 he arrives at the death-rate of 58·7 per cent. In the same

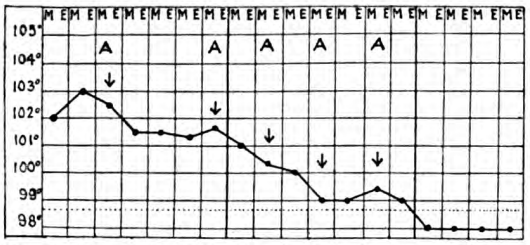
paper Dr. Routh gives another table showing that for the first six months of 1911 there were 145 cases notified in the Administrative County of London, having a death-rate of 46·9 per cent. It is interesting to note that in the same period there were in the London Hospital 28 cases notified (and therefore included in Dr. Routh's figures), having a death-rate of 25 per cent.

The mortality shown in Table III. appears to coincide fairly accurately with the mortality amongst the untreated cases in the series we are considering, namely, 55 per cent., if we remember that amongst these are included an excess of the milder cases which reduce the mortality. I desire, however, without placing too much importance on these figures, to put our results on record and to indicate briefly what appear to me to be justifiable conclusions.

Of the 56 cases treated 38 lived while 18 died, giving a mortality of 32 per cent. Of the 44 cases untreated 20 lived while 24 died, giving a mortality of 55 per cent. As I have already stated, these are not strictly comparable cases, as those untreated include on the one hand a few of the severest cases where death occurred before any specific treatment could be commenced, and on the other hand many comparatively mild cases. The bias, however, is rather towards lowering the mortality amongst the uninoculated owing to the excess of the mild cases. More valuable evidence can, however, be obtained if we consider those cases only in which there was definite bacteriological evidence of a blood infection. By this I mean either a positive blood culture or pyæmic abscesses from which a streptococcus was obtained in pure culture. Amongst those treated there were 28 such cases, Nos. 1–13 and 39–53. No. 52 did well for a time and had a normal temperature for a week. She was then allowed up. On the second day of getting up she was suddenly taken ill and she died in half an hour from heart failure. I omit this case therefore from my figures. Of the other 27 cases 13 lived (1–13) and 14 died (39–51 and 53), giving a mortality of 52 per cent. It should be noted that amongst these 27 cases counted as treated are included 6 which only received a single dose of a vaccine within 24 hours of death.

Turning now to the similar series of untreated cases, we have 16 examples—Nos. 57, 58, 77–89, 95. Of these, 2 lived (57, 58) and 14 died (77–89, 95), giving a mortality of 87·5 per cent. Further, if we confine ourselves to streptococcal cases we have 12 out of 13 cases untreated dying—mortality, 92 per cent. It would appear, therefore, that treatment by inoculation with vaccines in this series of cases has reduced the mortality by 30–40 per cent. How far this will be borne out in larger series of cases will be seen in the future, but



Temperature chart of Case 15, showing the mean of six 4-hourly temperatures and spacing of injections of vaccine. (A A mark injections of vaccine.)

these figures suggest that the benefit is sufficient to justify a continued and more extended trial of the treatment.

The length of time occupied in the treatment of these cases is a question which doubtless will be inquired about.

Roughly speaking, it appears from our series that the cases may be divided into three groups:—

1. Those which respond at once to an inoculation of a vaccine, the temperature falling to normal within 48 hours. Case 3 is a good example of this. Previously to inoculation there were streptococci in the blood stream and the temperature had varied between 101° and 104° F. for four days. Following on the first inoculation the temperature fell; within 24 hours the maximum was 102°, and in 48 hours it was normal. Recovery was uninterrupted.

2. They may respond to each of a series of injections, the average of the six 4-hourly temperatures falling a degree or so. Case 15, a chart of which is given, shows this well.

3. The temperature may steady until the daily maximum is not above 102°. Further injections fail to reduce this. In these cases there is probably a local collection of pus which must be found and drained; the temperature will then quickly fall to normal. No. 12 illustrates this well. Previously to inoculation the patient had 17 rigors in 16 days; the daily temperatures varied between 100°–106°. After the first injection the rigors ceased entirely, and the temperature subsided until the daily maximum was 102°. It remained thus for some three weeks, further injections having no influence. An abscess then pointed in the buttock. Immediately on opening and draining it the temperature fell to normal and did not rise again.

Conclusions.

1. The mortality amongst those cases of puerperal septicæmia in which there is definite bacteriological evidence of bacteria in the blood stream is from 85 to 95 per cent.

2. This mortality may by inoculation with autogenous vaccines be reduced to about 55 per cent.

3. The mortality amongst notified cases of puerperal fever is about 60 per cent.

4. This mortality may by inoculation with appropriate vaccines be reduced to about 30 per cent.

5. In cases of puerperal sepsis, if it is decided to explore the uterine cavity the opportunity should not be lost of obtaining a culture at the same time.

6. In the treatment of puerperal sepsis "stock" vaccines give inferior results, and should only be used when an autogenous vaccine cannot be obtained.

I desire, in conclusion, to express my thanks to Dr. Russell Andrews, under whose care the majority of the cases have been; also to some other members of the staff of the London Hospital for permission to make use of cases under their care. Further, my thanks are due to Dr. W. Bulloch, in whose laboratory I have carried out this work.

York-street, W.

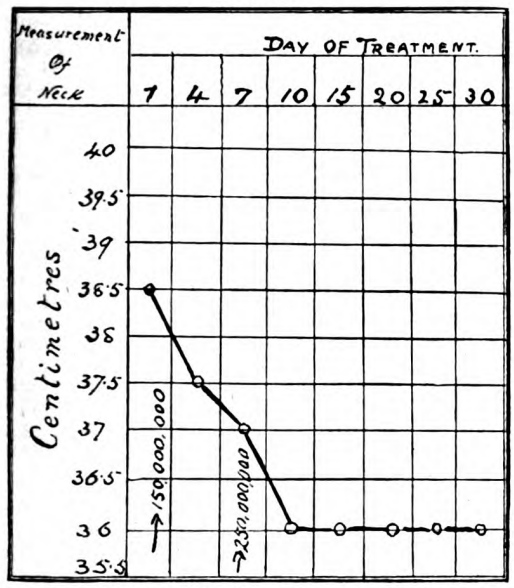
THE FINSBURY MEDICAL SOCIETY AND THE SHOREDITCH AND FINSBURY TUBERCULOSIS DISPENSARY.—The members of the Finsbury Medical Society have entered a protest against the formation of this dispensary on personal and general grounds. They consider that as soon as a decision was made to establish a dispensary in the neighbourhood a meeting of the whole of the medical profession of the district should have been called, so that the methods upon which the institution was to be worked could be explained to them and discussed. But they feel that, apart from personal feeling, there are reasons why they should object to give their coöperation to the Shoreditch and Finsbury Dispensary at the present time. When the National Society for the Prevention of Consumption first began to ask for public assistance in promoting tuberculosis dispensaries there was no National Insurance Act and no compulsory notification of phthisis. It is clearly stated in the Insurance Act that some such scheme as a tuberculosis dispensary should be established, and they point out that directly an insured person or any of his dependants is certified to be tuberculous, he can no longer claim "medical benefit," and is at once transferred to "sanatorium benefit," when the Government in return for contributions which have been paid has undertaken to provide treatment. If the Commissioners decide to recognise the existing tuberculosis dispensaries and finance them it is probable that the medical officers will be called upon to give expert opinion as to whether a compulsorily certified case is a suitable one for treatment in a sanatorium. The medical officer of the dispensary may feel it his duty to examine all contacts, and so draw numerous young people not yet insurable into the meshes of the dispensary for treatment. The question to be answered is, Under whose control shall the management of these dispensaries be:—(1) outside voluntary agency; (2) municipal control; or (3) local medical practitioners? The members of the Finsbury Medical Society came to the conclusion that the local practitioners should staff the dispensaries themselves, with the assistance of a resident medical officer. "It is time," they add, "that the idea that a general practitioner has forgotten all the medicine he ever learned was exploded."

THE VACCINE TREATMENT OF SIMPLE GOITRE.*

BY ROBERT McCARRISON, M.D. R.U.I., M.R.C.P LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE.

HAVING shown in the course of my researches on the etiology of endemic goitre that the infecting agent of this disease exists in the intestinal tract, and that a plentiful amœbic infection was present in this situation in the vast

CHART 1.



Showing measurements of neck at various stages of treatment, also doses and times of administration of vaccine.

majority of all cases of goitre in Gilgit,† [1 2 3] I have been engaged in endeavouring to cultivate amœbæ from the fæces of sufferers from this disease. During the course of this work I was struck with the constant character of the bacillary growths which appeared in the medium I employed. This medium was that recommended by Musgrave [4] for the cultivation of amœbæ and has the following composition: Beef extract 0·5 gramme, sodium chloride 0·5 gramme, agar

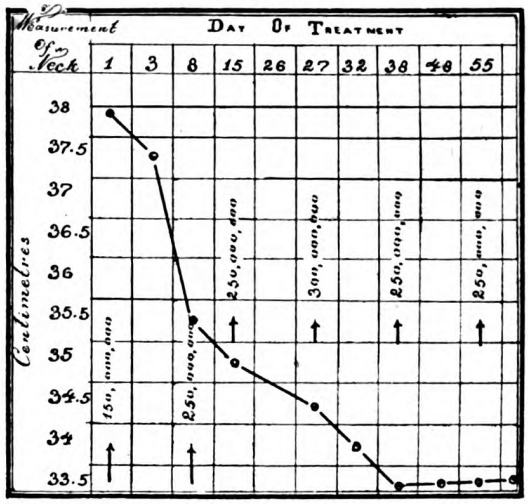
FIG. 1. FIG. 2.

Case 5. Diminution in circumference of neck = 2·5 centimetres.

20 grammes, tap water 1000 c.c., and is of an alkalinity of minus 1. It occurred to me to prepare a vaccine from such bacteria as grew on this medium and to employ it, as an experimental procedure, in the treatment of recent cases of goitre. At this stage of my investigations no attempt was made to isolate any particular organism. The vaccine employed was, therefore, a composite one and contained organisms capable of growth on an alkaline and feebly nitrogenous medium. This vaccine was administered in selected cases in doses of from 150,000,000 to 350,000,000; the inoculations were made at intervals of from seven to ten days. The results obtained were most striking. The following cases (Nos. 5 and 10) will serve as illustrations.

CASE 5.—Age of patient: 19 years. Occupation: water-carrier. Type of goitre: uniform parenchymatous. Circumferential measurement of neck over the goitre: 38·5 centimetres. Duration of disease: 6 weeks. Treatment: composite vaccine prepared from organisms grown on Musgrave's medium from his own fæces. Number of inoculations: 2. Duration of treatment: 10 days. Result: complete disappearance of the goitre. Final measurement of neck: 36 centimetres. Diminution

CHART 2.

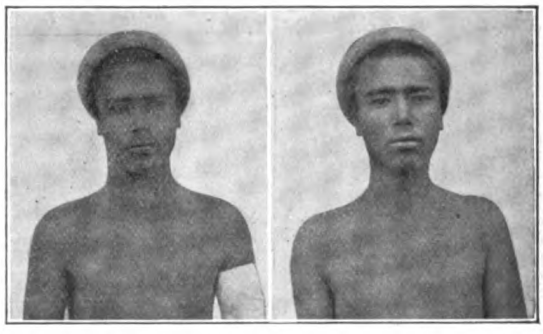


Showing measurements of neck at various stages of treatment, also doses and times of administration of vaccine.

in circumferential measurement of the neck: 2·5 centimetres. The patient carried on his work as regimental water-carrier during the whole course of treatment. (Chart 1, Figs. 1 and 2.)

CASE 10.—Age of patient: 19 years. Occupation: coolie. Type of goitre: parenchymatous, two small adenomata in right lobe and one in isthmus. Circumferential measurement of neck over the goitre: 38 centimetres. Duration of disease: 2 years approximately. Treatment: composite vaccine prepared from organisms grown on Musgrave's medium from his own fæces. Number of inoculations: 6. Duration of treatment: 60 days. Result: disappearance of goitre with the exception of the small adenomata in right lobe and isthmus. Final measurement of neck: 33·5 centimetres. Diminution in circumferential measurement of neck: 4·5 centimetres. The patient carried on his

FIG. 3. FIG. 4.



Case 10. Diminution = 4·5 centimetres.

work as a coolie during the whole course of treatment. (Chart 2, Figs. 3 and 4.)

It was then noted that the bacterial growth on the medium referred to was composed, as a rule, almost wholly of a bacillus which presented the characteristics of the coli group. This bacillus differed, however, from the typical "bacillus coli" in so far that it did not produce indol, and that it decolourised the litmus on a saccharose medium instead of reddening it. I am indebted to Major W. F. Harvey, I.M.S., of the Pasteur Institute of Kasauli, for working out the characteristics of this organism.

A vaccine was prepared from the bacillus, and I employed

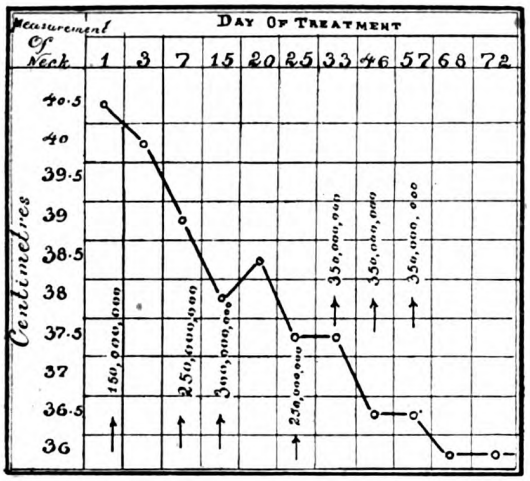
* A paper read before the Medical Section of the Royal Society of Medicine on Jan. 23rd, 1912.

† The superior figures throughout the article relate to the bibliography at the end.

it in 16 selected cases of goitre. The initial dose was in each case 150,000,000. The dose was gradually increased by 50,000,000 till in some cases a maximum dose of 350,000,000 was reached. The inoculations were made at intervals of from seven to ten days. Cases 11 and 12 are amongst the 16 cases treated in this way.

CASE 11.—Age of patient: 28 years. Occupation: priest. Type of goitre: parenchymatous, adenoma about size of a pigeon's egg in right lobe. Circumferential measurement of neck: 40·5 centimetres. Duration of disease: "many years." Treatment: autogenous vaccine made from the coliform organism referred to in text. Number of inoculations: 7. Duration of treatment: 72 days. Result: disappearance of goitre with the exception of the tumour in right lobe. Final measurement of neck: 36 centimetres. Diminution in circumferential measurement of neck: 4·5 centimetres. This man, prior to treatment, acted as a control to the previous case (Case 10); while so acting his goitre increased somewhat in size. (Chart 3, Figs. 5 and 6.)

CHART 3.



Showing measurements of neck at various stages of treatment, also doses and times of administration of vaccine.

CASE 12.—Age of patient: 23 years. Occupation: milkman. Type of goitre: uniform parenchymatous; small nodular mass in isthmus. Circumferential measurement of neck: 42 centimetres. Duration of disease: "about one year." Treatment: vaccine from Case 11. Number of inoculations: 7. Duration of treatment: 56 days. Result: complete disappearance of the goitre with the exception of the small nodular mass in isthmus. Final measurement of neck: 37·5 centimetres. Diminution in circumferential measurement of neck: 4·5 centimetres. The patient followed his usual avocations during the whole course of treatment. (Chart 4, Figs. 7 and 8.)

FIG. 5. FIG. 6.

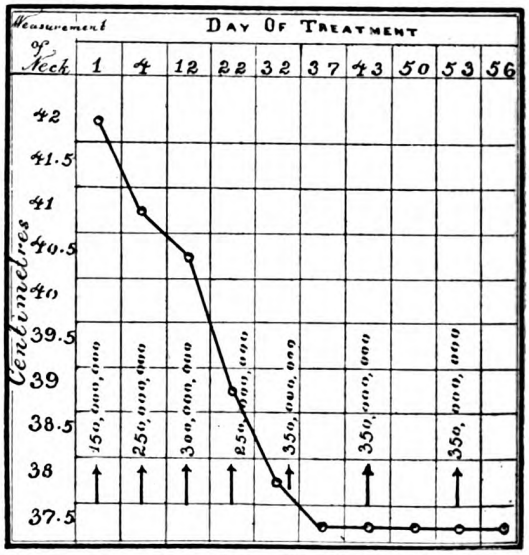
Case 11. Diminution = 4·5 centimetres.

At this stage of my observations I had in hospital four cases of caries of bone. I had obtained from each of these a staphylococcus, the vaccine prepared from which had proved highly efficacious in causing the bone to heal and the sinuses to close. It occurred to me to use this staphylococcic vaccine in the treatment of goitre. I consequently administered it in four cases. The initial dose was in each case 250,000,000; the inoculations were made at intervals of a week to ten days. In two cases the result was practically *nil*, but these were cases—one adenomatous, the other cystic—in which no form of medicinal treatment could have been of use. The other two cases, however, responded to the treatment in a highly satisfactory way. The following (Case 23) is one of these cases.

CASE 23.—Age of patient: 35 years (?). Occupation: policeman. Type of goitre: uniform parenchymatous. Circumferential measurement of neck: 39 centimetres. Duration of disease: "about two years." Treatment: staphylococcic vaccine; the staphylococcus was obtained from a case of caries of the femur. Number of inoculations: 5. Duration of treatment: 60 days. Result: complete disappearance of goitre. Final measurement of neck: 36 centimetres. Diminution in circumferential measurement of neck: 3 centimetres. The patient carried on his work as a policeman during the whole course of treatment. (Chart 5, Figs. 9 and 10).

About this time an Australian pony, recently imported into

CHART 4.



Showing measurements of neck at various stages of treatment, also doses and times of administration of vaccines.

Gilgit, was found to be suffering from goitre. The swelling was right-sided, about the size of a hen's egg, and was of not more than three weeks' standing. I isolated from the fæces of this animal a spore-bearing organism, the characters of which I have recorded in another place.[5] This organism was also commonly met with in cultures made from human fæces. Having satisfied myself, by the inoculation of small quantities of live cultures into animals, that its introduction under the skin gave rise to no ill effects, I employed a

FIG. 7. FIG. 8.

Case 12. Diminution = 4·5 centimetres.

vaccine made from this bacillus at the Pasteur Institute of Kasauli in the treatment of two selected cases of goitre. Here again the result was satisfactory. Case 33 is one of the cases treated in this way.

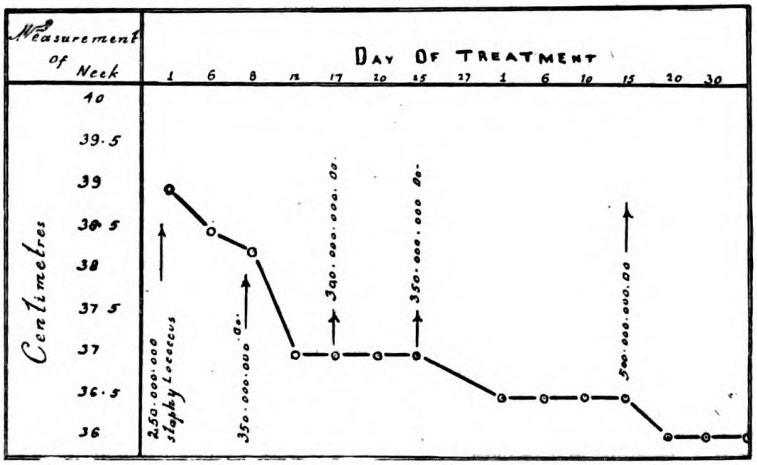
CASE 33.—Age of patient: 23 years. Occupation: cultivator. Type of goitre: parenchymatous; two small tumour masses in right lobe. Circumferential measurement of neck: 41 centimetres. Duration of disease: "over a year." Treatment: vaccine prepared from spore-bearing organism referred to in text. Number of inoculations: 4. Duration of treatment: 40 days. Result: disappearance of goitre with exception of two tumour masses in right lobe. Final measurement of neck: 37·5 centimetres. Diminution in circumference of neck: 3·5 centimetres. The patient carried on his work as a cultivator during the whole course of treatment. (Chart 6, Figs. 11 and 12.)

Forster's dysentery vaccine was then tried in two cases,

but without any beneficial result. One of these subsequently responded to vaccine with the composite vaccine referred to at the beginning of this paper.

I have treated 33 cases of simple goitre by means of vaccine. The cases were selected cases. The results observed may be summarised as follows. Of the four vaccines which were successfully employed the "composite" vaccine appears to be the best, though, as will be seen from the photographs and charts which illustrate this paper, the other three vaccines have given excellent results. I have found an initial dose of 150,000,000 to be most suitable in the case of the composite vaccine and in the case of that prepared from the coliform bacillus referred to. There is usually some rise of temperature a few hours after the inoculation, but this is rarely of any severity if the initial dose does not exceed 150,000,000. Subsequent dosage can be readily regulated by the effect of the treatment on the enlarged thyroid. When the gland begins to soften and the skin over it to become lax the dose which has brought about the result will not need to be increased at subsequent inoculations. I believe, also, that the volume of the vaccine inoculated should be small, and that it is better to introduce 150,000,000 of the bacteria in 5 minims of salt solution than in 1 cubic centimetre of the same. The local reaction does not then appear to be so marked, and when the upper arm is selected as the site of inoculation the patient is usually able to follow his ordinary avocation with no more loss of time than that necessary to attend at the laboratory for the treatment.

CHART 5.



Showing measurements of neck at various stages of treatment, also doses and times of administration of vaccines.

Cases vary considerably as to the number of inoculations which are necessary to effect a cure. As a general rule, it may be said that the older the goitre the larger the number of inoculations which will be needed. I have had several cases in which the thyroid swelling has entirely disappeared after two or three inoculations (Case 5, Figs. 1 and 2). As a rule, however, from four to seven inoculations were found to be necessary.

This treatment is suitable for cases of recent parenchymatous goitre, and its value is confined to such cases. It has little or no effect where the goitre is of long standing—that is to say, when the main part of the swelling is made up of adenomata or of cysts. In some cases a shrinking of the thyroid tissue around adenomatous or cystic masses is observed, but no diminution in the size of these masses has been noted to occur.

All my patients have commented on the feeling of *bien être* to which this treatment gives rise, and so popular had it become—by reason of its simplicity and its freedom of restrictions of diet, &c.—before I left Gilgit, that my last five or six cases asked for it in preference to any other. I have usually employed an autogenous vaccine, though I have obtained excellent results by using the vaccine of one patient for the treatment of another (Case 12, Chart 4, Figs. 7 and 8).

With this treatment—as with the treatment of goitre by thymol, iodine, or the bacillus bulgaricus—the patients, as a rule, lose flesh and the skin becomes of a healthier tint. I am of opinion that the loss of flesh is to be thus explained. The toxic agent of the disease is destroyed or inhibited in its action by the vaccine or by the internal medication; in consequence, the secretion of the hypertrophied organ is for a time in excess of the demand. The excess of secretion, therefore, which continues to be thrown into the blood stream, until such times as the gland regains its normal equilibrium, exerts its influence in increasing the metabolic processes of the body and a loss of subcutaneous fat is the result.

It will, perhaps, be remembered that I have produced goitre experimentally in man by the administration of matter separated from a goitre-producing water by means of a Berkefeld filter.[2,3] I repeated this experiment in five young men whose goitres had been cured by vaccination. In no case did the thyroid gland show the slightest increase in size, though the five individuals consumed the "suspended matter" for a period considerably longer than the subjects of my original experiments. It is possible, therefore, that these men may have been in some measure protected by this vaccination, since having once suffered from goitre they would have been more likely to acquire it than individuals who had not been previously so afflicted.

Now there arises out of this treatment of simple goitre the problem that vaccines prepared from no less than three bacteria—namely, a coliform bacillus, a spore-bearing bacillus, and a staphylococcus—have been employed with success in causing the hypertrophied thyroid to return to its normal size. The solution, I believe, is to be found in an application of Metchnikoff's discovery that certain microbes of our normal intestinal flora are harmful by reason of the poisonous substances which they produce in the intestines. These organisms are of the coli group, certain spore-bearing organisms, and the staphylococcus. By their action on proteid food-stuffs they produce poisons—indols and phenols—which are absorbed by way of the intestinal wall and give rise to fibrotic changes in the liver, kidneys, and arteries. It did not occur to Professor Metchnikoff to note the action of these poisons on the thyroid gland, though he concluded that they exercised a harmful influence on most of the organs of the body.[6]

FIG. 9. FIG. 10.

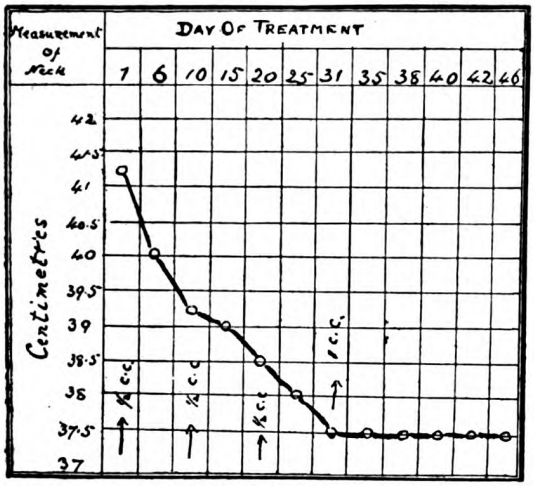
Case 23. Diminution = 3 centimetres.

The vaccines which I have employed were prepared from organisms similar to these normal and harmful inhabitants of the intestines. There is at present no evidence that any one of these possesses a specific influence in the production of goitre. The conclusion, therefore, is suggested that the thyroid gland is called upon to combat several poisons normally present in the human intestine. When to these is superadded the specific virus of goitre an abnormal element is introduced and an extra strain is thrown upon the gland. Unassisted, it undergoes hypertrophy in many cases, but if assisted in any one direction it is capable of performing the additional task which has been imposed upon it and of combating the abnormal virus. On the assumption

that no one of the different vaccines which I have employed contains the specific organism of goitre my explanation of their action in this disease would be that they cause the disappearance of the goitre by relieving the thyroid of part of its normal work, thus enabling it, without continuing in a state of hypertrophy, to destroy the specific toxin of goitre.

The vaccine treatment of goitre which I have described leads us to two important conclusions. In the first place, it confirms the view of the etiology of the disease which I enunciated several years ago—namely, that goitre is due to the presence of a living organism of disease in the intestinal

CHART 6.



Showing measurements of neck at various stages of treatment, also doses and times of administration of vaccines.

tract[1,2]; and secondly, it demonstrates that the thyroid gland is markedly influenced by the nature of the bacterial flora of the intestine, and that one of its chief functions is to protect the body from the many toxic substances which find their way into the blood stream from the alimentary tract. This latter conclusion is substantiated by some experimental work which I have lately published.[5] The experiments show that the thyroid glands of goats undergo marked changes as a result of the continued contamination of their food with cultures of micro-organisms grown from the fæces of goitrous individuals.

Now, apart from the significance which attaches to the action of vaccines on the hypertrophied thyroid when

FIG. 11. FIG. 12.

Case 33. Diminution = 3·5 centimetres.

considered in relation to the etiology of goitre, I desire to emphasise the importance of the antitoxic action of the thyroid mechanism. Assuming the accuracy of the second of my conclusions, we at once appreciate the *raison d'être* of this mechanism in the human economy. We realise that the gland undergoes hypertrophy as the result of a definite stimulus, which is commonly toxic material absorbed from the alimentary tract, and also that the enlargement is not an evidence of derangement of the organ's function, but of its effort to resist some toxic agency. For my own part, I believe that the nervous and other degenerative changes which follow as a result of thyroid incompetency are due to the action of poisonous substances absorbed chiefly from the alimentary canal. These poisons, by reason of the functional imperfection of the thyroid, are allowed free play on the unprotected tissues of the body, and such conditions as tetany, cretinism, and myxœdema are the result.

I claim that my researches on the etiology of goitre have established the importance of the antitoxic action of the thyroid mechanism and I would venture to suggest that future researches upon its diseases should take this action as their fundamental basis.

THE FATE OF THE APPENDIX AFTER ABSCESS FORMATION.[1]

BY A. P. DODDS-PARKER, F.R.C.S. ENG.,
SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD.

WHEN some six years ago I had the honour of opening a discussion before this society on the treatment of appendicitis, and after stating that the aim of the surgeon should be to drain an abscess rather than to look for the appendix, Dr. W. Collier asked what was the condition of the appendix if a second operation was subsequently performed. To this query there were then no satisfactory replies. I said I would, however, try to investigate this as being very important—(1) in order to be able to give advice to patients who had recovered from an attack of appendicitis with abscess formation, where the abscess had been successfully drained, and the cavity healed; and (2) what the advice should be—that is, was one justified in allowing the patients to continue with the appendix still *in situ* without warning them of the possible dangers connected with this state of affairs?

At the time Dr. Collier raised this question I could but quote Sir Frederick Treves, who in the "Text-book of Surgery," vol. ii., p. 628 (1898), says: "As a matter of fact, after an abscess has once formed very little more is heard of the appendix." Since this date I have been able to collect 17 consecutive cases for analysis, which are tabulated in the accompanying table.

I must here apologise for not having all the appendices, too, for inspection, but owing to an accident the jar in which they were stored has been disturbed and most of the labels became displaced. The consequence is, we were unable to identify many of them when going over the appendices, and I think it is wiser to tell the truth than produce a number of these organs which one cannot vouch for. As you will realise, the investigation has taken a long time, lasting over six years, and although the result seems small it has necessitated much searching through notes in hospital.

I have altogether looked over 250 cases, and the first result one sees is the comparatively small number of cases which have had abscesses opened and drained, and gone on to a subsequent operation. This is to be accounted for by: (1) the great majority of the cases one now sees are either (*a*) acute and early or (*b*) quiescent, with operation of appendectomy performed, and, of course, these do not come under discussion in this paper; and (2) the difficulty of persuading hospital patients to return for a second operation after they leave the institution convalescent and feeling no symptoms of their former complaint. The number of private cases was large, and is to be accounted for in this manner. I find the private patient much more inclined to take one's advice than is the hospital patient, who so often thinks one wishes to "experiment" on him.

Before I take up in detail the table of cases I think it will be interesting to mention the literature on this subject. I will at once state that it is, as far as I can find out, scanty in the extreme.

At a discussion raised on the subject at the Royal Medical and Chirurgical Society[2] in 1905 Sir Frederick Treves is reported as saying: "I was at one time disposed to think

[1] A paper read before the Oxford Medical Society on Dec. 8th, 1911.
[2] Transactions of the Royal Medical and Chirurgical Society, vol. lxxxviii., p. 429.

the patient who had had a perityphlitic abscess was, *ipso facto*, cured of his malady, and that although he might have further trouble with the abscess he need fear no other attack of definite appendicitis. Longer experience has shown this assumption is not correct." (*Vide* Nos. 9, 8, and 6.) Sir Douglas Powell at the same discussion says: "If a diseased appendix is left behind there is a great risk of abscess formation and general peritonitis, with 25 per cent. mortality compared with 2 per cent. for simple operation."

Battle, in THE LANCET of July 4th, 1908, p. 79, states it is much more to the point to produce evidence which will carry weight with the unprejudiced observer of the present time, based on clinical and pathological grounds, and quotes seven cases in his paper (Jan. 18th, 1902).

In Kelly's book on appendicitis—a large and elaborate treatise—I can find no mention of the subject, nor in most of the journals or other books I have looked up. However, in the most recent "Operative Surgery" at the Radcliffe Infirmary I find an important paragraph written by G. H. Makins in Burghard's "System of Operative Surgery" (vol. ii., p. 492). He says: "The appendix can rarely be removed simultaneously with incision and drainage of an abscess. The significance of the appendical abscess as an indication for subsequent appendectomy has been much discussed. It has been asserted that the local abscess protects

Table of Analyses of 17 Consecutive Cases—1905 to 1910.

No.	Age.	History of attacks.	Nature of primary operations.	Nature of final operation.	Condition of appendix.	Result.	Remarks.
1	34	No history of previous attack before abscess formation. Operation for abscess 14 days after onset of symptoms.	Abscess formation. Drained. Pus about ℥ iv. evacuated.	Rectus route. Appendix found and removed. Adhesions.	Little destruction of appendix. End bulbous.	Recovery.	Went out 3 weeks after final operation.
2	27	Onset of symptoms 10 days before operation.	Abscess formation. Drained. Pus ℥ i evacuated.	Discharging sinus, rectus route. Appendix found and removed. Firm adhesions to iliac crest.	No destruction of appendix.	,,	Discharged 3 weeks after final operation.
3	21	Large pelvic abscess 14 days after first attack.	Abscess formation. Drained per rectum, Jan., 1906.	Rectus route. Appendix found and removed by abdominal route.	Little destruction of appendix. Strong adhesion to bladder.	,,	—
4	12	No previous attack. Pain for 14 days.	Abscess formation. Drained. Small quantity of pus evacuated.	Rectus route. Appendix found and removed. Some adhesions.	No destruction of appendix.	,,	Discharged 3 weeks after final operation.
5	14	Six days' pain before he was operated on for abscess.	Abscess formation. Drained. Right iliac fossa drained on April 30th. Left iliac fossa drained on May 2nd.	Rectus route. Appendix found and removed. Adherent at tip.	,,	,,	Discharged 4 weeks after final operation.
6	20	In 1902 had serious peritonitis at school. Second attack 5 years after in Switzerland.	Peritonitis and abscess formation. Drained.	Quiescent stage. Appendix found and removed. Adherent to scar of old wound. Ventral hernia operation.	Appendix not in any way destroyed.	,,	Ventral hernia cured by muscle sliding at same time.
7	21	Four days ill.	August 1st, abscess opened and drained. Not much pus.	Rectus route. Appendix found and removed 25 days after draining. Adherent.	No destruction of appendix.	,,	Discharged 24 days after final operation.
8	30	First attack August, 1905. Refused operation. Large pelvic abscess burst per rectum, 1907. Second attack no abscess.	No operation in first two attacks, but abscess burst per rectum in first attack.	1908, Acute attack. Appendix found and removed. Strong adhesions into pelvis.	,,	,,	—
9	14	Three days' history of pain before first operation.	Two attacks of abscess formation, both treated by drainage.	After subacute attack, in quiescent stage, appendix found and removed. A few adhesions.	No real destruction of appendix, which was lying behind cæcum and adherent in pelvis.	,,	Ventral hernia cured by muscle sliding. This case was operated upon twice.
10	14	Abscess one year previously, treated at W——.	? Drainage.	Ventral hernia. Appendix found and removed, pointing retrocæcally.	No destruction of appendix.	,,	Discharged 30 days after final operation. Ventral hernia cured at same time by muscle sliding.
11	9	Attack in 1909 with abscess formation.	Opened and drained.	Appendix found and removed. Adhesion at apex.	*Fæcal concretion* impacted at end.	,,	—
12	9	In 1908 had multiple abdominal abscesses which required two operations.	Opened and drained on two occasions. On third, abscess burst per rectum.	Appendix found and removed. Adherent by strong adhesion at tip only.	No destruction of appendix.	,,	Ventral herniæ cured at same time by muscle sliding.
13	—	Pain for 8 days before abscess operation.	Abscess formation. Opened and drained.	Rectus route. Appendix found and removed. Appendix lying far back in pelvis. Adherent.	No destruction of appendix, which was long and rather chronically inflamed.	,,	Discharged 35 days after final operation. Wound healed slowly.
14	24	Pain for 8 days, two previous attacks.	Abscess opened and drained. Large quantity of pus.	Appendix found and removed. Many adhesions.	No destruction of appendix. Chronic inflammation.	,,	Discharged 24 days after final operation.
15	4½	General peritonitis.	Multiple drainage tubes.	Appendix found and removed.	No destruction of appendix.	,,	Abdominal herniæ cured by muscle sliding.
16	27	—	May, 1910. Abscess formation. Opened and drained.	Nov., 1910. Appendix found and removed. Adherent behind cæcum. Acute kink.	No destruction of appendix. Acute kink with *fæcal concretion*.	,,	—
17	30	—	July. Pelvic abscess. Opened and drained.	Nov. 25th. Appendix found and removed. Adherent.	No destruction of appendix.	,,	—

from future attacks. However, future attacks are more probable than in cases where repeated attacks of a milder type have led to cicatrisation or atrophy of the organ?" Page 517: "Mortality after operation for local abscess, 13·4 per cent." Of cases which recovered and had been followed up there were recurrences in 39·9 per cent., and 70 per cent. of these recurrences were accompanied by fresh suppuration. In 18 cases a subsequent interval operation was performed, and in all the appendix was found capable of giving rise to fresh attacks. All the cases recovered.

Let me now say a few words about the cases I have tabulated, and in so doing I will take the headings.

1. *Age.*—You will note that all the cases are of young people. This is accounted for by the fact that this disease is commoner in the young, and that when an abscess has been opened and drained in an elderly person I have not advised a second interval operation, but have told the patient to await a second attack and then have an immediate operation. In young people, however, I have always advocated a subsequent interval operation, as they are more likely to be in inaccessible places when another attack occurs—Canada, Switzerland, &c.

2. *History of attacks.*—Here is one of the strong reasons in my opinion for an interval operation as soon as convenient. Out of 17 cases there were multiple attacks in Nos. 6, 8, 9, 16, and, if I may mention another case, A B (9), who had an abscess opened and drained in 1902; in 1904, peritonitis and two operations, appendix not removed. In 1911 I heard from the mother that he had had another severe attack in France, and asking if the appendix had been removed and whether I advised its being taken away if it had not. In these cases you will see that sometimes several years elapsed between abscess formation and a fresh attack. (Nos. 6 and 8, and A B.)

3. *Nature of primary operation.*—In all cases drainage only, as now advised by the majority of surgeons. Most of the cases did not come into the surgeon's hands till more than a week after onset of symptoms. Under these circumstances the abscess cavity is usually well defined and the appendix almost impossible to find and remove. When one is able to get at the cases before 48 hours there is rarely any difficulty in doing this, and in the great majority of cases now sent into hospital we see them before the third day of disease (often much earlier), and hence the difference in the nature of the operation.

4. *Final operation.*—Not difficult as a rule. Route: Rectus in all cases on account of the possible difficulties from adhesions; but in the majority of cases these were conspicuous by their smallness. They were marked in Nos. 6, 8, and 16, when I think any other incision would have made the removal extremely difficult, but I do not propose discussing these incisions here. One most remarkable thing to me is the absence of many adhesions in such cases as Nos. 3, 9, and 12. Difficult cases are usually those with numerous subacute attacks.

5. *Condition of appendix.*—(*a*) Found and removed in all cases. (*b*) No obliteration of lumen. (*c*) Fæcal concretions in two cases (Nos. 11 and 16 and ? No. 9). (*d*) No destruction of appendix as a whole. (*e*) Gross anatomical and pathological changes, such as kinks, scarring, and strictures.

6. *Results.*—Recovery in all cases. In fact, the present mortality of appendectomy in the "interval" stage is, if anything, below 2 per cent., as already stated.

7. *Ventral herniæ.*—These are in my experience frequent after the drainage of abscess through the abdominal wall—A B, Nos. 6, 9, 10, 12, and 15. So that one is able to remodel the abdominal wall as well as remove a diseased appendix.

Therefore the general conclusions I am able to state are:—1. The appendix was never destroyed but was damaged. 2. There was decided liability to fresh attacks with such diseased organs in the belly. 3. In the present keen struggle for existence it is wiser to remove such a menace to life. 4. The danger of a second operation is not great, and herniæ may at the same time be cured. So far mortality *nil*.

In conclusion, I would like to state that these 17 cases are in no way picked, but are taken over a number of years out of 250 cases, just as they came under my care, and I am deeply disappointed that I am unable to show you the whole series of the appendices, but that is not my fault but misfortune.

Oxford.

A CASE OF TUBERCULOSIS WITH SPECIAL INVOLVEMENT OF THE HEART.

BY PHILIP BAHR, M.A., M.B., B.C., D.T.M. & H. CAMB.;
AND
GEORGE C. LOW, M.A. ST. AND., M.D. EDIN., C.M.
(*From the London School of Tropical Medicine.*)

AFFECTIONS of the heart wall are comparatively rare in tuberculosis; therefore we offer no excuse for publishing the following interesting details of such a case.

The patient, a Fijian female, about 25 years of age, was admitted to the Colonial Hospital, Suva, Fiji, under the care of Dr. G. W. A. Lynch, chief medical officer, Fiji, on Nov. 28th, 1910, suffering from hæmoptysis. On admission the following notes were made. Temperature irregular, rising from normal to 99° or 100° F. at night, with a morning fall frequently as low as 96°. The patient was very weak, emaciated, and very anæmic, ascites also being present. An examination of the respiratory system gave well-marked signs of tuberculosis at both apices, similar physical signs being found lower in the lungs as well, while at the bases behind a considerable quantity of fluid was present. As regards the circulatory system, the heart was greatly enlarged, the apex beat lying in the fifth space almost at the anterior axillary line, while the borders in the other directions also lay much beyond their normal limits. On auscultation the cardiac sounds were very indistinct, but a systolic murmur could be detected at the base of the organ.

FIG. 1.

Heart showing the outside appearances specially. The nodular tubercular masses are well seen. N, Nodules or tubercular masses.

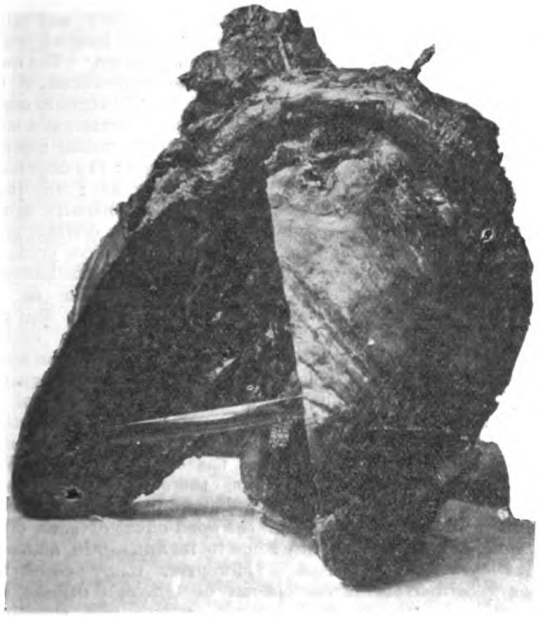
This murmur did not appear to be conducted. The abdomen was prominent, fluid evidently being present. Of the abdominal viscera the spleen appeared to be normal, but the liver was enlarged, feeling hard to the touch, though not nodular, while the lower edge was easily palpable. The urine was acid, of specific gravity 1020, albumin being present in considerable quantity, but no blood or sugar. The patient rapidly went downhill and died from heart failure on Dec. 12th.

At the necropsy performed by Dr. F. N. Smartt next day the following pathological lesions were found. The pericardial sac contained an excess of straw-coloured fluid. There was no pericarditis, the membrane not being thickened, but it was adherent to the surface of the heart at the base.

No tubercles were detected on it. The heart was very large, weighing 37 oz. on removal. It presented a most unusual appearance, the walls both of the auricles and ventricles being studded with nodular masses of the shape and size of small marbles. The organ was not opened at the time of the necropsy, but was preserved and brought to England entire. Both pleural sacs contained a great excess of clear straw-coloured fluid. On the right side many adhesions bound the lung to the chest wall, while numerous miliary tubercles could be seen dotted over the pleural membrane on both sides. On section fairly advanced tubercular lesions, from miliary tubercles up to caseating masses of the size of hazel nuts, were found scattered through both lungs. The apices were both involved. The bases of the organs behind showed considerable œdema.

Of the other viscera, the liver was hard, bile-stained, and typically nutmeg; it weighed 56 oz. The spleen was

FIG. 2.



The cavities of the heart have been more widely opened. The enormously thickened caseating wall of the left ventricle is well seen, and the very small ventricular cavity.

normal. Both kidneys contained a few miliary tubercles, while large caseating areas were found in the mesenteric glands and miliary tubercles were scattered over the peritoneum. Many typical tubercular ulcers were found scattered throughout the small intestine. The brain was not examined.

So far, then, the necropsy notes show that the case was one of tuberculosis of the lungs with a spreading general infection, the unique features being the extraordinary condition of the heart.

Description of the heart.—The heart was brought home from Fiji preserved in formalin and was opened and studied soon after its arrival at the London School of Tropical Medicine. The accompanying illustrations give some idea of the extraordinary lesions found in its walls after section and render a minute written description unnecessary. The left ventricle, perhaps more so than the other chambers of the heart, was greatly diminished in size owing to an enormous, more or less concentric, hypertrophy of the ventricular wall. The myocardium showed an extraordinary appearance, being infiltrated, or rather replaced, by caseous, cheesy masses of different sizes, these having produced the nodular or marble-like lumps seen on the outside of the heart during the necropsy. Fig. 1 shows these well. The wall at the base of the ventricle measured no less than 1¾ in. in thickness, this gradually tapering to ¾ in. at the apex. Practically no normal muscular tissue was left, the tubercular lesions having entirely replaced this. Fig. 2 illustrates these points.

The right ventricle and both auricles were also affected, the cavity of the left auricle especially being surrounded and infiltrated by tubercular masses and thereby greatly obliterated. Remains of pericardium adherent and firmly bound to the auricles and great vessels at the base were easily found, but, as already mentioned, the pericardial membrane was, on the whole, quite free from tubercular changes.

The case furnishes an excellent example of a tubercular myocarditis, and with such advanced caseous masses replacing almost entirely the whole muscular substance of the heart it is extraordinary how life could have been prolonged as long as it was. The caseation and cheese-like masses were quite typical of tubercle, but to make absolutely certain of this sections were cut both of these and the lesions in other parts of the body. Histologically these showed typical tubercular lesions, and by Ziehl Neelsen's method tubercle bacilli were detected in large numbers in the material taken from the heart.

In conclusion, we must state how greatly indebted we are to Dr. Smartt for his kindness in allowing us to publish this case.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

"PANNICULITIS."

BY WILLIAM BAIN, M.D. DURH., M.R.C.P. LOND.

FOR the past dozen years I have met patients who declined to continue massage on account of the pain it produced. This hyperæsthesia I thought then was purely neurotic. During the last few years I have had a number of these cases. On examination it was found that the hyperæsthesia was generally limited in extent and distributed in patches. The patches occur most frequently on the abdomen, next in order of frequency on the legs, arms, and back, and occasionally on the thorax. I will attempt to describe a patch. If you pick up the skin and subcutaneous tissue over it and roll them between the fingers they feel somewhat firmer and less elastic than the normal structures. The slight infiltration is either in the deepest layers of the corium, or in the subcutaneous tissue, or in both. Judging by tactile sensation my impression is that the inflammatory deposit is in the subcutaneous tissue. The sensitive areas are generally smooth, about 1 or 2 inches in diameter, and very tender on pressure. If the pressure is applied perpendicularly to the surface the tenderness is slight, but if applied from the circumference of the sensitive area it is very marked. A patch is evidently an aggregation of smaller ones. When the patch is disappearing under massage it splits up into several smaller ones, and the thickening therefore becomes uneven. The contour of the smaller patches can be made out, and before they finally disappear they feel like small pin-heads. These sensitive deposits occur chiefly in neurotic patients. Most of the patients are females about the middle period of life, and are inclined to be stout. I will briefly mention the last two cases I saw during the autumn.

Mrs. A, aged 46, gouty, had a hæmorrhage on the left side of the brain 12 years ago. The systolic blood pressure was 150, and the weight 12 st. She was somewhat neurotic. She had a single patch in each upper arm; both were very painful when massaged.

Mrs. B, aged 48, had appendicitis four years ago; no operation on account of the feeble condition of her heart. The heart was slightly dilated and the pulse was weak. The systolic blood pressure was 99, and the weight 14 st. 12 lb. The patient was not in the least neurotic. She had four patches on the abdomen which were very painful on pressure.

It is difficult to give an accurate description of the condition, as there is so little to feel. In the case of Mrs. B the exudations would probably have escaped observation were it not for the pain produced on examining the abdomen.

The pain is evidently produced by the pressure of the inflammatory deposits upon the nerve endings.

As I believe the infiltration occurs in the panniculus adiposus I should be inclined to coin a word and call it "panniculitis." The condition is apparently quite distinct from fibro-myositis, although the two are sometimes associated. In one of my cases the masseuse had to disperse the thickening in the panniculus adiposus before attempting to massage the indurated muscle immediately underneath on account of the tenderness caused by the manipulations.

Dr. W. H. Maxwell Telling,[1] in a most interesting paper entitled "Nodular Fibro-myositis," does not differentiate between panniculitis and induration of the muscles. One of the cases he describes (No. 4) was, I think, an example of panniculitis. Further, in my experience panniculitis occurs more frequently in gouty than in rheumatic subjects.

Regarding treatment, massage is the only effective remedy. I have tried thyroid extract, but I am not satisfied as to its therapeutic utility in this affection.

Harrogate.

A CASE OF COMPLETE LOSS OF MEMORY—? AFTER INFLUENZA.

BY H. S. GASKELL, M.B., CH.B. EDIN.,
HONORARY MEDICAL OFFICER TO THE COBHAM COTTAGE HOSPITAL.

THE following case may, I venture to think, be of interest to readers of THE LANCET.

On Jan. 16th I was called to see a young man, aged 22 years. I found him in bed complaining of feeling seedy and having a cough and sore-throat. He lay very still, muffled up in the clothes, and seemed rather depressed. The duration of the illness had been four days. Up to the 15th he had been attending to his duties as usual. He had never had any illness, and the only medical attention he had ever received had been for measles and chicken-pox in childhood. My examination proved negative. The temperature was normal and the pulse was of low tension and regular in force and frequency. The fauces and uvula were very slightly, if at all, reddened. The tongue was very slightly furred at the back. The action of the heart and lungs appeared to be normal. I prescribed calomel and a mixture containing sulphate of magnesia and nux vomica. On the 18th I saw the patient again, when he was up and dressed. He said he felt better, only a "bit slack." On the 22nd (Monday), although not yet feeling quite up to the mark, he started out to walk to his place of employment, a distance of half a mile. He walked about 200 yards, and remembers addressing some remark to a boy on the road, and after that his mind became an absolute blank. The next thing he remembered was sitting, in a state of complete exhaustion, on a seat at Hampton Court, nine miles away. He asked where he was, and then having just enough money in his pocket, he came back by train, went to bed, slept straight off for 13 hours, and woke up feeling much better. He was kept in bed for five days, although he felt well, and a full diet, with extra milk and eggs, was recommended. He has now resumed his duties and appears to be perfectly well.

The "trance" began approximately at 8.45 A.M. and ended at about 3.45 P.M. The patient stated that on awaking he had a violent headache, and felt very tired and cold. He was so cold that he thought he must have been sitting still for some time. The weather at the time was damp and rainy, but not very cold. He had never been near Hampton Court before. He must have walked along a main road (the Portsmouth road), along which flows a constant stream of motor traffic, and must have passed through the congested district of Kingston-on-Thames, with all its trams and crossings. It would be interesting to hear of any other experiences of the sort.

Cobham, Surrey.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

The Vaccine Treatment of Goitre.

A MEETING of this section was held on Jan. 23rd, Dr. FREDERICK TAYLOR, the President, being in the chair.

Captain R. MCCARRISON, I.M.S., read a paper entitled, "The Vaccine Treatment of Simple Goitre," which is published in full on p. 357 of this issue of THE LANCET.

Dr. F. PARKES WEBER asked whether thyroid feeding produced diminution of the goitre in the class of cases which Captain McCarrison had treated. One would expect it to do so if the explanation offered were correct.

Dr. FREDERICK LANGMEAD said that anyone who had followed Captain McCarrison's work on goitre and allied conditions could have counted beforehand on hearing something of importance and interest that afternoon. The question which the reader of the paper had introduced, of the relationship between the thyroid gland and toxæmic conditions, was a very broad and intricate one. Amongst a large number of examples of this relationship he would mention three groups of cases in which it occurred: (1) conditions connected with uterine and ovarian function; (2) rheumatoid arthritis; and (3) tetany. It was generally agreed that the thyroid gland enlarged at puberty, during pregnancy, and during the menstrual periods, which could be regarded as minor and abortive pregnancies, and that signs of thyroid incompetence were not uncommon at the menopause. Evidence was accumulating to show that this enlargement was not merely associated with ovarian activity, but was brought about by the presence of an active agent in the blood. This agent in the case of pregnancy was thought to be actually transferred to the blood of the newly-born child, in whom it caused mammary secretion, vaginal hæmorrhage, or prostatic activity. By Halban it was believed to be a product of the chorionic villi. With regard to rheumatoid arthritis, there was considerable evidence to show that it might be produced by absorption of toxins from the bowel, and the good effect of such drugs as guaiacol was ascribed by some to its antiseptic action on intestinal micro-organisms. Moreover, many cases had been recorded of the association of Graves's disease and rheumatoid arthritis, and thyroid extract was sometimes very efficacious in the treatment of the latter. Tetany had been mentioned by Captain McCarrison. Now tetany, as it occurred in young children, was almost invariably preceded by abnormal loose or offensive motions. In adults it complicated dilatation of the stomach and Bouveret and Dévic had isolated a toxin which could produce tetany from the stomach contents in such cases. The speaker himself had recorded other cases of tetany in children, associated with dilatation of the colon, which appeared to be analogous. That there was a relationship between tetany and the thyroid gland was well known. These remarks only conveyed a few ideas bearing on the connexion between thyroidal enlargement and toxæmia—a very big subject.

Mr. JAMES BERRY said that he thought the profession was rapidly coming to the conclusion that all cases of goitre were due to a toxic influence, and that chemical changes in the water were not the cause. Whatever the toxic agent was, it was suspended in the water used for drinking. The treatment of parenchymatous goitre was essentially medical, but there remained other forms to be dealt with by the surgeon. He hoped that vaccines might be another valuable means of medical treatment. He was convinced that no surgeon should operate upon simple parenchymatous goitres until they had been efficiently treated by medical means for a considerable time. It could not be expected that medical treatment would benefit patients suffering from adenomata. He did not agree that hypertrophic and parenchymatous goitre were synonymous terms. The latter was a condition of atrophy rather than of hypertrophy. The vesicles were filled with secretion, but it was stagnant and the cells were inactive. He asked whether any diarrhœa was produced by treatment.

The PRESIDENT said that, as various medical methods were

beneficial in parenchymatous goitre, it was to be expected that there was some underlying factor which was common to them all. Had Captain McCarrison thought whether there was anything in common in the methods of operation of arsenic, iodides, thyroid extract, and vaccines?

Dr. ROBERT HUTCHISON said that although no one could deny Captain McCarrison's therapeutic results he was not so sure about the validity of his explanation of them. He was always rather sceptical about intestinal intoxication and thought that it was too often advanced as an explanation of all sorts of obscure conditions. All they knew of the secretion of the thyroid tended to show that it was a great stimulant of oxidation in the body, and those conditions in which a physiological hypertrophy of the thyroid occurred, such as pregnancy, were perhaps conditions in which there was an increased metabolism and a demand for more thyroid secretion to meet it. This explanation was quite as likely as that there was an increased toxæmia. On the other hand, there was much more reason to regard the liver as the organ concerned with the destruction of poisons passing from the portal system. He would like to know how long the beneficial effects of vaccine lasted in these cases.

Dr. F. G. CROOKSHANK asked what kinds of goitre were prevalent in Gilgit, and whether they showed any tendency to spontaneous cure? Did endemic cretinism occur?

Captain MCCARRISON, in reply, said that no diarrhœa had occurred in his cases. No recurrence had taken place over a period of two years in some of them. He thought that the common factor in the various forms of treatment lay in the truth that they all assisted the thyroid in its antitoxic function. Goitre in the Gilgit Valley was like goitre elsewhere. Cretinism was very common there and goitre occurred in 40 per cent. of the cretins. He had never seen a goitre of any standing disappear spontaneously. 20 per cent. of recruits imported to that district became goitrous and a few got well without treatment when the enlargement was very slight.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Radical Cure of Inguinal Hernia in Children.—Exhibition of Cases and Specimens.

A MEETING of this section was held on Jan. 26th, Dr. G. A. SUTHERLAND, the President, being in the chair.

Mr. DOUGLAS DREW showed a case illustrating the Late Result of Muscle-transplantation for the Relief of Talipes Valgus. The peroneus brevis had been transplanted to the tibialis posticus by passing it across, beneath the tendo Achillis, and over the other tendons at the inner side of the ankle. The operation had been most successful in remedying the valgus, but a slight degree of varus had supervened. Reference was made to other cases in which a similar result had been obtained.

Dr. THEODORE THOMPSON showed two brothers with Hæmophilia. The first shown was a poorly nourished boy 10 years old. The symptoms had been present from infancy, and bruising had been usual on very slight trauma; if he scratched his hand he would bleed for an hour. Sometimes there was slight bleeding from the mouth. For several years he had had attacks of pain and swelling in the knees. Coagulation time five minutes. The second boy was aged 5 years, stout, and well nourished. Extensive bruising of the skin and deeper structures occurred on very slight injury. The only family history of bleeding was on the mother's side.

Dr. ERIC PRITCHARD and Mr. SYDNEY STEPHENSON exhibited a case of Cerebellar Tumour. Five years ago the patient had received a blow on the head. Three years ago he had vomited for no apparent cause, and since then he had been subject to intermittent attacks of headache, vertigo, and sickness, which were preceded by optic prodromata, which usually took the form of fortification spectra with a brilliant range of colours. There was slight incoördination in walking, and Romberg's sign was present. The pupils responded to light, both directly and indirectly. There was hippus, especially in the left eye. When the eyes looked straight at an object, as, for example, the ophthalmoscopic mirror, they jerked slightly up and down. There were also jerking movements on looking inwards, outwards, and upwards, and double papilloedema without inflammatory signs or retinitis.

Dr. R. C. JEWESBURY showed a case of Deformity of the Chest in a girl aged 12 years. The mother first noticed "something wrong" with the shoulder 10 months ago. The child had had a severe fall down 15 stairs when 3½ years old, and was considerably hurt at the time. The upper part of the right side of the chest was much flattened, the first and second ribs were sunken, and bony thickening was felt on these ribs below the clavicle. The pectoral muscles on the right side looked wasted, but there was no loss of power. The radiogram showed a bony outgrowth from the first rib projecting downwards and articulating with a similar growth from the second rib. Cervical ribs, well developed on the right side, were present.

Dr. JEWESBURY also showed three cases of Hemiplegia. The first patient was a boy, aged 4 years, a full-time child. Labour had been prolonged, but no instruments had been used. The child had been weak down the right side from birth, and subject to fits, chiefly affecting the right side, causing twitching, with loss of consciousness. There was marked atrophy of the right side of the face, with weakness of the right face, and right arm and leg, the hand and foot cold, and shortening of the right leg. The patient in the second case was a girl, aged 7 years, with weakness down the left side which had been noticed when she was 7 months old. Fits of epileptic type affecting the right side were first noticed five months ago. The left arm and leg were much wasted, and there was marked loss of power with shortening of both arm and leg. In the third case, that of a boy aged 4 years, loss of use in the right hand and arm had been noticed for about one month. Squint was first noticed six months ago. There was marked loss of power in the right hand and arm; the arm was usually held straight downwards and kept stiff. The patient walked with the feet wide apart and kept the right leg stiff. There was weakness in the right leg. Elbow-jerk and knee-jerk were increased if obtained when muscular spasm was relaxed. The boy was backward and his speech was difficult to understand.

Dr. F. PARKES WEBER showed a case of Congenital Pulmonary Stenosis without Cyanosis in a boy 6 years of age. The heart was somewhat in excess of the normal size, and over the præcordium was heard a harsh systolic murmur, with its maximum intensity over the pulmonary area, to the left of the sternum.

Dr. EDMUND CAUTLEY exhibited a case of Lymphatism in a boy aged 6½ years. The boy was tall for his age. There was an area of dulness over the manubrium sterni extending more to the left than the right, with some general enlargement of the lymphatic glands and spleen; and adenoids and hyperplasia of the circumvallate papillæ. The heart-beat was slow, the pupils were large, the complexion was pale, and the skin was thin, with an excess of subcutaneous fat.

Mr. J. P. LOCKHART MUMMERY showed a case of Shortening of the Left Femur in a boy aged 7½ years. The presentation had been a breech, and at two weeks of age "something wrong" was noticed with the left leg. For two years the boy had worn a high boot, and there did not appear to be any increase in the shortening in that time. The left leg was 1½ inches shorter than the right, and this was practically entirely in the femur. The angle of the femur was slightly reduced on the left side. It was considered that the shortening might be due to an injury to the upper femoral epiphysis at birth.

Dr. CAUTLEY exhibited a specimen of Tuberculous Tumour of the Dura Mater in a child aged 14 months.

Mr. PHILIP TURNER read a paper on the Radical Cure of Inguinal Hernia in Children. The object of the paper was to bring forward a modification of the usual operation for this condition, and by the method the least possible damage was inflicted upon the inguinal canal, and the sac was efficiently removed. The operation which Mr. Turner performed is as follows:—The external oblique aponeurosis is exposed by a short incision above Poupart's ligament, external to the external abdominal ring. A short ½ inch incision is made through the aponeurosis just above the middle of Poupart's ligament; the internal oblique is retracted, and the cord, covered by the cremaster, exposed just below the internal abdominal ring. By blunt dissection the cord and sac are drawn through the small incision in the external oblique; the sac is readily isolated and ligatured at the internal ring and removed, the small incision in the external oblique aponeurosis being closed with a few catgut sutures.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION.

Bubonic Plague.

A MEETING of this section was held on Jan. 25th at 15, Cavendish-square, W., Dr. G. H. THOMPSON (Buxton), the President, being in the chair. About 20 members and visitors were present.

Dr. F. M. SANDWITH read a paper entitled "Bubonic Plague" (illustrated by the epidiascope).

Dr. P. ABRAHAM remarked that the important rôle which the lower animals played in the spread of disease was one of the most notable advances in knowledge in recent times, and he believed that the number of diseases so spread would be recognised to be greater in the near future. He instanced leprosy, the bacillus of which would probably be found to be identical with the acid-fast bacillus discovered by Mr. Dean some few years ago in rats. Dr. Bayon was now writing upon this subject, and his observations so far tended to prove the truth of this view.

Dr. S. D. CLIPPINGDALE expressed his grateful appreciation of Dr. Sandwith's instructive and interesting paper. Referring to the matter mentioned by the President, the outbreak of plague at Eyam in 1665, he had visited the place, and was interested to learn that the vicar had not only placed a cordon round the affected area, but outside this cordon had placed a tank of water into which money was placed to pay the people who brought food for the cloistered plague-stricken inhabitants, thus showing on the part of the reverend gentleman a commendable knowledge of the requirements of sanitation.

Mr. W. J. MIDELTON (Bournemouth) said he thought he had heard Dr. Sandwith say that pus organisms killed off plague bacilli in the buboes. If so, did not this raise the question that pus organisms might be beneficial in certain circumstances?

Dr. LIEVEN (Aix-la-Chapelle) mentioned how important was the study of zoology for employment in practical bacteriology, as, for instance, the bacillus typhi murium (mouse typhoid) discovered by Löffler, which attacked only certain mice, and it was luckily that species most commonly found to which it has a predilection.

Dr. E. SOLLY (Harrogate) and the PRESIDENT also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Jan. 12th, Dr. T. G. MOORHEAD being in the chair.

Dr. W. D. O'KELLY exhibited specimens from a case of General Tuberculosis with some unusual features. The patient, a female child, aged 11 years, died with every sign before death, confirmed post mortem, of generalised tuberculosis, but Dr. O'Kelly was unable to demonstrate tubercle bacilli in the affected tissues. Numbers of sections were stained by the Ziehl-Neelsen method, especially those from the lungs, spleen, and liver, with a negative result. Even the anti-formin method was unsuccessful. The dairy from which the girl perhaps became infected may be traced, and tubercle bacilli demonstrated in the milk supplied by it.

Dr. W. G. HARVEY gave a short clinical history, with an account of the morbid anatomy of a case of Addison's Disease, and showed specimens and sections. The patient was admitted to the Adelaide Hospital under Dr. H. T. Bewley on May 22nd, 1911, complaining of weakness and vomiting. She had never enjoyed very robust health. In 1897 her foot had been amputated for tuberculous trouble. Subsequently she began to suffer from pain along her spine, which continued with intermissions until February, 1911, when she became noticeably weak. The weakness increased for a couple of months, when the following symptoms supervened: Insomnia, loss of appetite, with palpitation and breathlessness on the slightest exertion. Constant pain in the stomach, uninfluenced by food. Frequent attacks of vomiting, usually in the morning, and often followed by fainting. General languor, mental and bodily, and failure of memory. On admission to hospital she appeared excessively weak. She was moderately well nourished, nor was there apparent anæmia. She lay sunken down in the bed, and answered questions drowsily without turning her face or eyes towards her interrogator. The skin of the face and hands, and more especially that of the axillæ and nipples, were darkly pigmented. Reflexes normal, slight nystagmus. Temperature irregular, generally subnormal, but rising to about 100° F. Pulse weak, tension low, rather rapid (100 per minute). A trace of albumin sometimes present. There was general tenderness over the abdomen. She gradually sank and died on June 16th, 1911. At the post-mortem examination very little abnormality could be made out by the naked eye, save completely caseous suprarenals, the darkly pigmented skin, and a markedly flabby heart. The microscopic examination showed the suprarenals to be entirely caseous, none of their normal structure being discernible. The skin showed dense masses of pigment, mostly situated in the deep layer of rete Malpighii. The heart muscle showed an extreme degree of "fragmentation." In addition to this a miliary tuberculosis was present in the lungs and liver, and tubercles were also present in the ovary. It would seem that this miliary tuberculosis, which had every appearance of being recent, must have come on shortly before the patient's death. The suprarenals, on the other hand, must have been tuberculous for some considerable time, and the history of the case would suggest their infection before the foot was amputated in 1897.

Dr. W. BOXWELL showed a specimen of Carcinoma of the Cardiac End of the Stomach.

Dr. K. E. L. G. GUNN showed two specimens from cases of Disease of the Bladder. He described the first as a typical warty carcinoma of the bladder occurring in a patient from whom a villous growth had been removed some years before, and at the time reported "innocent." Both ureters were widely dilated and thickened, and both kidneys pyonephrotic. The patient from whom the second specimen was taken had been thought to be suffering from enlarged prostate. He was moribund on admission, and the post-mortem examination proved death to be due to general septic peritonitis. In the bladder were found three calculi, one in each of two lateral pockets, giving the organ the shape, and to the touch the sensation, of a large prostate gland. The third calculus had caused a perforating ulcer of the fundus and consequent peritonitis. It was the first case of the kind Mr. Gunn had seen.

SECTION OF STATE MEDICINE.

Sterilisation of the Mentally Unfit.—Causation of Insanity in Ireland.

A MEETING of this section was held on Jan. 19th, Dr. T. P. C. KIRKPATRICK being in the chair.

Mr. M. J. NOLAN read a paper on the Proposed Sterilisation of the Mentally Unfit, in which he advanced the calculation that this line of treatment, when confined to reproductive cases of reproductive ages, only amounted to some 7 per cent. of the asylum population on any given date. He invited the attention of his hearers to the probable bad effects of these operations on the mental condition of these recoverable cases, and also the probable evil effect on the healthy husband or wife of such recovered cases. He dwelt on the fact that the lines of mental inheritance follow no very definite lines, and that the sterilisation of the unfit of one generation was no guarantee for the degree of fitness in the next. He pointed out that this aspect of the question became more involved when the observations made recently at the Epileptic Village Colony at Skelman, U.S.A., were taken into account. There it was noted that the mating of persons nervously unstable with those mentally deficient produced 50 per cent. of normal offspring, so that such paradoxical results would tend to reinforce the sound stocks, and that as the natural law was the survival of the fittest, nature always kept the degenerates in the minority. In conclusion, he held that sterilisation was a premature proposal, and that much could be done by legislation touching education, syphilis, drink, marriage of defective, and pathological research in mental disease, to accomplish the reduction in the number of the insane, so much to be desired by all.

Mr. R. R. LEEPER read a note on the Causation of Insanity in Ireland. He stated that in the course of his experience he found that in cases of insanity who did not recover, and in whom recovery was not complete, a hereditary taint was nearly always present. In Ireland the most potent cause in

the production of insanity was the unreformed Poor-law system. None of the recommendations by the Royal Commission upon the Feeble-minded could be carried out without Poor-law reform. The workhouses of Ireland continued to receive a number of defective and feeble-minded women, who gave birth there to numbers of illegitimate children who were defective, and thus a steady stream of degenerates was yearly poured into the general population. The married habitual pauper's children were reared in workhouse atmospheres, and developed into criminals or degenerates of one kind or another. Medical men did not preach eugenical ideas, and people entered into marriages without due consideration of the matter from a eugenical standpoint. People considered eugenics a very admirable science, but it had no bearing whatsoever upon their own individual lives.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A special meeting of this society was held on Jan. 19th, Mr. H. Littlewood, the President, being in the chair.—Dr. E. F. Bashford, director of the Imperial Cancer Research, gave an address on "Some Aspects of the Cancer Problem."—There was a clinical demonstration of cases of malignant disease which had remained free from recurrence for seven years or longer after operation.—Dr. A. Hawkyard showed a patient in whom the right half of the tongue, with glands, had been removed by Mr. Lawford Knaggs over nine years ago.—Dr. H. H. Greenwood showed a case of Duct Cancer of the Breast successfully operated upon in 1897, and a second case of scirrhous cancer operated on in 1899. In both cases Halstead's operation was performed.—Dr. A. Christy Wilson showed: (1) A patient who was operated upon by Mr. Pridgin Teale in 1881 for carcinoma of the breast; and (2) a man from whom he had removed a sarcoma of the upper jaw in 1898, the growth being of the size of a Tangerine orange and small-celled. The whole of the left upper jaw, including the orbital plate, left tonsil, pillars of the fauces, &c., was removed.—The President gave a demonstration of patients whom he had operated on for malignant disease at the Leeds Infirmary during the period from 1896 to 1905. The number was 190. These were written to by Mr. E. T. Willans, Mr. Littlewood's house surgeon. Only 69 replies were received. Of these 23 patients are now alive and well. Six patients lived more than seven years and died without any recurrence, 23 died within two years from recurrence, and 17 died from recurrence at longer intervals. So that out of 190 cases, 29 are known to have lived for seven years after the operation without any recurrence—i.e., about 15 per cent. The cases shown were: Sarcoma of clavicle, 1; sarcoma of testis, 2; sarcoma of upper jaw, 3; sarcoma of breast, 1; carcinoma of breast, 5; carcinoma of colon, 5; and carcinoma in other parts, 6.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held at Paddington Green Children's Hospital on Feb. 1st, Dr. H. J. Macevoy, the President, being in the chair.—The following cases were shown:—Dr. Leonard G. Guthrie: (1) Transposition of Viscera and Dextrocardia; (2) Right Cerebellar Tumour; and (3) Chronic Jaundice with Splenomegaly.—Dr. G. A. Sutherland: (1) Achondroplasia; (2) Congenital Heart Disease; (3) Acute Polioencephalitis; (4) Cardiac Disease with Rheumatic Nodules; and (5) Tuberculous Peritonitis.—Dr. R. Miller: (1) Infantilism with Renal Disease; and (2) Acute Poliomyelitis.—Mr. A. Edmunds: Congenital Absence of Femur.—Mr. M. S. Mayou: (1) Sympathetic Paralysis of Right Eye; and (2) Congenital Word Blindness.—The cases were discussed by various members.—Some interesting microscopical slides were also shown in the new pathological department by Dr. H. W. Perkins.

A CORRECTION.—Professor W. D. Halliburton writes to say that Dr. J. Burdon-Cooper's statement at the Ophthalmological Society meeting, reported in our last issue on p. 297, is not quite correct. Professor Halliburton did not confirm the presence of tyrosin in the aqueous. The crystals examined by Professor Halliburton in 1906 looked something like tyrosin, but the amount present was insufficient for analysis. The subsequent account of the investigation of the lens of a pig's eye was given, of course, by Dr. Burdon-Cooper, and referred to his own work.

Reviews and Notices of Books.

Pathologische Anatomie. Ein Lehrbuch für Studierende und Aerzte. Bearbeitet von L. ASCHOFF, Freiburg i. Br.; M. ASKANAZY, Genf; H. BEITZKE, Lausanne; C. BENDA, Berlin; M. BORST, München; A. DIETRICH, Charlottenburg; P. ERNST, Heidelberg; E. v. GIERKE, Karlsruhe; L. JORES, Köln; R. KRETZ, Würzburg; O. LUBARSCH, Düsseldorf; O. NAEGELI-NAEFF, Zürich; R. RÖSSLE, Jena; M. B. SCHMIDT, Marburg; H. SCHRIDDE, Freiburg i. Br.; E. SCHWALBE, Rostock i. M.; M. SIMMONDS, Hamburg; O. STERNBERG, Brunn. Herausgegeben von L. ASCHOFF, Freiburg i. Br. Zweite Auflage. Jena: Gustav Fischer. 1911. Erster Band: Allgemeine Aetiologie, Allgemeine Pathologische Anatomie. Pp. 778. Price, paper, M.14; bound, M.15.75. Zweiter Band: Spezielle Pathologische Anatomie. Pp. 997. Price, paper, M.16; bound, M.17.75.

To the editor it appeared impossible for one person to write a text-book on general *and* special pathology without devoting his whole time to it, and hence he summoned to his aid trusty and well-equipped collaborators.

Volume I. deals with general pathology, and it begins with an article by R. Rössle on General Ætiology and the Causes of Internal Diseases. M. Askanazy then deals with the Causes of External Diseases, and Rössle contributes a chapter on the General Pathology of the Cell. The rest of the volume is devoted to general pathological anatomy, and is divided into chapters in which are treated successively the following subjects: Malformations, by E. Schwalbe; Disturbances of Metabolism, by E. v. Gierke; Diseases of the Circulatory System, by A. Dietrich; Immunity and Allied Phenomena, by R. Kretz; Inflammation, by O. Lubarsch; and Pathological Growths and True Tumours, by M. Borst.

It is impossible to do more than single out a few of the salient features in a work which is so admirable throughout. The part devoted to heredity is particularly well done and well illustrated, and we commend its perusal to pathologists. The causes of external diseases, such as the effects of heat, cold, electricity, light, X rays, atmospheric pressure, traumatisms, infections, chemical toxins, poisons, and auto-intoxications, are all skilfully and compactly handled. Parasites—first the vegetable forms—as the cause of disease are next considered. The coloured illustrations are particularly fine, both as regards sharpness of definition and truthful reproduction of the staining—good examples are those of pneumococci, gonococci, sarcina; of the bacillus of anthrax, tetanus, influenza, typhoid, tubercle, and leprosy; of treponema pallidum of Schaudinn in syphilis blackened by silver nitrate by the Levaditi colouration. Animal parasites belonging to the protozoa, vermes, and arthropoda are next considered, and are equally lavishly and successfully illustrated. There are also life-like illustrations of trypanosomes and the malarial parasites. The general pathology of the cell is well illustrated in colour, including Negri's corpuscles in nerve cells, giant cells, and degenerations in general.

A section of their studies not much pursued by students is that of general teratology, which in this volume is treated in a most attractive manner by E. Schwalbe. It includes comparative teratology as well as human abnormalities. The figures are excellent—e.g., those of cephalothoracopagus of various kinds, of holoacardius as seen by the X rays, and such strange forms as diprosopus, craniopagus, abnormalities which find their explanation in the facts of embryology. The chapter on disturbances of metabolism is illustrated by 31 figures. Such outstanding subjects as death (general and local), necrosis, atrophy, degenerations are concisely set forth. The derangements of fatty and of

mineral metabolism are equally well discussed and illustrated —e.g., siderosis, argyrosis, anthrakosis, and rickets. There are excellent figures to illustrate the text on the circulatory organs. One is very striking—viz., that of an embolism of the pulmonary artery resulting from thrombosis of the femoral vein.

Under the head of "Protective Inoculation and Immunity" there is a full account of serum therapeutics, agglutinins, precipitins, anaphylaxis, cytotoxins, and allied subjects, and particularly well set forth and illustrated is the theory of immunity. The chapter on Inflammation and the illustrations are good, and the same may be said of the chapters devoted to Pathological Growths and True Tumours.

Volume II. concerns itself with special pathological anatomy. The editor, Professor Aschoff, deals with the heart, female reproductive organs, the digestive and urinary organs. C. Benda is responsible for the blood-vessels and the lymph-vessels. O. Naegeli treats of the blood and Schridde of the blood-preparing organs. H. Beitzke gives an account of the respiratory organs, and P. Ernst of the nervous system. The male reproductive organs are allotted to M. Simmonds; the liver and pancreas to C. Sternberg; glands with internal secretions to E. v. Gierke; the skin to L. Jores; and the motor apparatus M. B. Schmidt.

In dealing with the special organs, in every case there is a preliminary chapter on the development, and the anatomy of the normal organ under consideration is briefly and tersely described. As in Volume I., the illustrations are excellent. In the chapters on the heart we may refer to the *a.-v.* bundle, brown and fatty degeneration of the heart fibres, and those of stenosis of the aorta and myocarditis. The figure of fatty degeneration of the aorta is particularly life-like. The description of the blood-preparing organs is good, and the illustrations are equally so. There are a number of figures in the chapter dealing with bones which we think are not usually found in text-books. They should commend themselves particularly to the surgeons. Some of the illustrations of the nervous system appear to be rather small and crowded with detail, while there are relatively fewer coloured illustrations than in the other sections. The pathology of the urinary organ is very well set forth, and the same may be said of the treatment of the digestive tract—a rather lengthy series of chapters.

We have said enough to show how excellent, comprehensive, and well illustrated this text-book is. We feel sure that it will be welcomed by all pathologists, both in the land of its birth as well as in foreign parts. Text, type, paper, and illustrations are all alike beyond cavil, and we congratulate the editor and his co-workers on the successful result of their combined efforts.

The Life of John Ruskin. By E. T. COOK. In two volumes. London: George Allen and Co., Limited. 1911. Vol. I., pp. xxv. and 540; Vol. II., pp. 615. Price 21*s.* net.

TO few men has it been given to have their thoughts and writings so criticised as have been those of John Ruskin. Almost every man of letters in this country for fifty years has had his say about the master, and we wonder that there is anything fresh to tell. Mr. Cook, we remember to have heard, used to tear the wrappers from the early numbers of "Fors" on his way from chapel to breakfast when a boy at school, and ever since those early days he has been in constant contact with Ruskin's mind and works. But to those elders who have almost forgotten the enthusiasms universally displayed with regard to Ruskin's earlier work, these volumes will come with pleasing freshness, and more modern students will find both cause and effect of Ruskin's work displayed intelligibly.

Much of the fascination and influence of Ruskin lay outside of his didactic criticisms and his more formal oratorical essays. He would have rested immortal upon the formulations of "Modern Painters" and "The Seven Lamps of Architecture" alone, but he was much more than an art critic, and perhaps the subject in which he attained the greatest accuracy of thought was geology. His latest biographer is free to touch upon personal matters with less reserve than Mr. Collingwood was able to do in 1893, and we are afforded pathetic glimpses of the failures and misfortunes of Ruskin's life. Details interesting to the psychologist of his repeated mental attacks are given with discretion and taste, and reference is made to the explanation given by Ruskin himself to a writer who communicated this account to the columns of the *British Medical Journal* of Jan. 27th, 1900. One notable feature in the attacks of mental storms was the vivid character of the visions and the exacerbation of the beauties and hideousness of things beautiful and hideous respectively. The writer of the article asked Ruskin if he did not think that this might be due to his (Ruskin's) highly developed artistic sense, to which Ruskin replied in the negative, but he also referred to the extremely vivid manner in which children could see what grown-up persons could not—e.g., resemblances in natural objects to something else which had no connexion with them. And herein may lie the explanation of Ruskin's vivid vision in illness. He had the mind of a child, with all its powers of imagination and ability to make real that which an adult would call unreal. His mental quality was always of that kind described by Thomas Treherne in writing of his childhood:—

> Then did I dwell within a world of light
> Distinct and separate from all men's sight,
> Where I did feel strange thoughts and such things see
> That were, or seemed, only revealed to me.

And this internal vision was sharpened in illness. But how human Ruskin could be when the bow unbent; what a charmingly naïve picture he gives of himself in Venice (Vol. II., p. 301): "I strike work at two or a little after—go home, read letters, and dine at three; lie on sofa and read any vicious book I can find to amuse me—to prevent St. Ursula having it all her own way. Am greatly amused with the life of Casanova at present." There is nothing of the prig here.

Ruskin's great charm lay in the vast range and versatility of his knowledge. No one, for instance, has written on the Psalms for ordinary lay British readers with the illuminating insight, that page after page of "Modern Painters" demonstrate. And "what a mirror of the author's mind is 'Fors' in its discursiveness! It ranges from Monmouth to Macedon, from China to Peru, from Giotto to goose-pie" (Vol. II., p. 319).

Without undue insistence and without apparent effort Mr. Cook has given us a loving and lifelike portrait of a most learned man, who owed most of his mental training to his own steadfastness, and to whom, although his views were at times Quixotic, his country owes a debt for his burning words in defence of truth, beauty, and that righteousness which exalteth a nation.

The British Pharmaceutical Codex, 1911: an Imperial Dispensatory for the Use of Medical Practitioners and Pharmacists. By direction of the Council of the Pharmaceutical Society of Great Britain. London: The Pharmaceutical Press. 1911. Pp. xiii.–1568. Price 10*s.* 6*d.* net.

THE progress that has been made in pharmacy during the past four years is well reflected in the new issue of the "British Pharmaceutical Codex," but the difference between the new issue and that of 1907 is by no means wholly due to the improved pharmaceutical methods that have been devised during the period intervening between the publication of the two issues. There is abundant evidence that information furnished as a result of pharmaceutical research

has been utilised fully in the new book, and the faults of the first issue—faults which it is almost impossible to avoid in the first edition of a technical book of this magnitude—have been corrected.

The arrangement of the new issue has the advantage of convenience. The 1907 issue traversed the long journey from Abri Semina to Zizyphus without a break, but in the new work the matter is divided into two parts, one containing the materia medica and the other consisting of the formulary. To the former 1100 pages are devoted and to the latter 334, the book containing 150 pages more than the previous issue. In the materia medica section the useful plan has been adopted of indicating by means of heavy type the important properties of the drugs described, and the same type has been used in other ways to facilitate reference. A further improvement is the addition of brief descriptive notes on the preparations of each drug and chemical, at the end of the respective monographs. Where drugs, chemicals, and galenical preparations described in the Codex are official in the British Pharmacopœia or the Pharmacopœia of the United States of America the fact is indicated, an indication which was lacking in the first issue. Reference is also made to the source of non-official preparations mentioned, and of some which were formerly official. By adding to the book a pharmacological and therapeutic index, the Codex Committee have rendered the work the most useful of the kind published in this country; to medical practitioners it will be most valuable.

Collected Papers by the Staff of St. Mary's Hospital (Mayo Clinic), Rochester, Minnesota. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 633. Price 24*s.* net.

WE had the pleasure of noticing in THE LANCET of August 19th, 1911, the first volume of reprinted papers by the members of the staff of the Mayo Clinic, and we are pleased to see that it has been thought well to issue in one volume all the papers which have been published during the year 1910 or thereabout. It is a good plan that might well be followed by other institutions, for a volume such as this gives a very good idea of the activity of the staff, and the reader is able to estimate the amount of work that has been done, and to compare it with the output of other similar bodies. It is not until all these papers have been collected that it is recognised how much has been done. In this volume the contents have been classified according to the organ concerned, and, as might have been expected, a large portion of the book, about half in fact, deals with the surgery of the abdomen. Our space will only permit a notice of the more striking papers.

Dr. H. S. Plummer contributes a paper on the Technic of the Examination of Œsophageal Lesions; it is illustrated by a large number of skiagrams showing the appearances presented by the different classes of lesions; the position, the shape, the size, and the relations of diverticula and dilatations when filled with bismuth mixture are shown clearly in skiagrams. Dr. Plummer speaks highly of Mixter's method of employing a silk thread as a guide: the patient swallows six yards of silk thread; this passes far enough down into the intestine to prevent its withdrawal when it is pulled taut, and if a hollow sound is slipped over its upper end it will be guided into the true channel of the œsophagus and will avoid pouches. Dr. Charles H. Mayo has also written a paper on the Diagnosis and Surgical Treatment of Œsophageal Diverticula, in which he discusses the technique of the recognition of these pouches, and he reports eight cases of this condition, six of which have been treated successfully at the Mayo Clinic; the two others have not had any operation performed on them. Dr. William J. Mayo has supplied a paper on the very important subject of Gastro-jejunal Ulcers, or, as they have been called, "pseudo-jejunal ulcers"—that is to say, ulcers forming at the gastro-jejunal opening. Three cases occurred, but not one case of true jejunal ulcer was met with after 1141 gastro-jejunostomies. Dr. Donald C. Balfour has reported 15 cases of Meckel's Diverticulum; these were found in 10,000 cases of abdominal section. In 5 of the 15 cases the diverticulum caused symptoms for which the patient sought relief, while in the 10 others the patients' symptoms were not due to the diverticulum, yet in a few of these active pathological changes were present in it.

Dr. William F. Braasch has written two papers on the Renal Pelvis in which he has discussed its deformities and the means of recognising them. A number of useful skiagrams accompany the articles. Dr. Louis B. Wilson has described 32 cases of Hypernephroma, and he has also contributed a paper, in the preparation of which he was assisted by Mr. Byrd C. Willis, on the histology of these tumours. He comes to the conclusion that hypernephromata do not arise from adrenal rests or from proliferations of the adult secreting epithelium of the convoluted tubes, as has been suggested, but are derived from "islands of nephrogenic tissues (primitive renal blastema)." The only other paper which we have space to mention is one on Pulmonary and Circulatory Complications following Surgical Operations, by Dr. E. H. Beckman. Four cases of pulmonary embolism are reported, and of these one recovered.

From the fact that many of these papers were written for reading before general medical audiences, it is not surprising that some of them are a little sketchy, but for the most part they are important contributions to surgery. There is certainly some overlapping when the same subject has been dealt with by two different writers, and even illustrations have been duplicated, but this is not of any great importance. We shall look forward with interest to future volumes of this series.

Ancient Types of Man. By ARTHUR KEITH, M.D., LL.D. Aberd., Conservator of Museum and Hunterian Professor, Royal College of Surgeons of England, &c. With frontispiece and 29 illustrations in the text. London and New York: Harper and Brothers. 1911. Pp. xix.–151. Price, cloth, 2*s.* 6*d.*; leather, 3*s.* 6*d.* net.

BY the publication of this little volume in "Harper's Library of Living Thought" Professor Keith has done a double service—a service to the science of anthropology and a service to the great collection of anthropological material which he has under his charge. Anthropology has benefited especially by the method which the author has chosen for presenting his subject, for he has given what is practically a catalogue of the remains of ancient man, so that material which is scattered through many museums and private collections is brought under the review of anyone who cares to spend 2*s.* 6*d.* on the volume. Yet the book is far from being a mere catalogue, for concerning each relic Professor Keith gives the circumstances of the discovery, the characters of the bones, and an able discussion of the probable type of individual represented by a few stray fragments of his skeleton. And withal the whole account is woven into one consecutive story, so that the reader may follow the succession of the early types of the human race from the late Neolithic Briton who ate blackberries in Essex back to that notorious individual who lived in Java in early Pleistocene days at latest.

The whole account is remarkably easy reading, and is given in plain language, which adds enormously to the utility of the book. This very simplicity is the key to the second service rendered by Professor Keith. In England

we have great storehouses of material wherein are kept—and all too often buried—treasures the value of which depends almost entirely upon a chain of apparently trivial details concerning their finding. These details are not infrequently within the knowledge of people ready and willing to furnish them, but unaware of their significance to the specialists who guard the treasures. The scientific gain that attends the awakening of interest in such subjects is not to be easily over-estimated, and Professor Keith has already amply demonstrated this fact in regard to the Gibraltar skull. Often some purely utilitarian work is done—a dock is dug out, a railway cutting cleared, or a gravel pit excavated; in some more fortunate places a scientist may be commissioned to watch the work. In England the observation of the chance finder of some human fragment often affords the only trustworthy data on which hinge questions of the utmost importance.

The man who places, in a form easy of mastery, the essential facts of our knowledge of the traces of early man within reach of the public has, therefore, done good service to his science, and in this case also to his office.

The Declining Birth-rate. By A. NEWSHOLME, M.D. Lond., M.R.C.S. London: Cassell and Co. 1911. Pp. 64. Price 6*d.* net.

OF the series of "New Tracts for the Times," promoted by the National Council of Public Morals, the present is the third in order of publication. Within the compass of its 64 pages the author has accumulated a surprising amount of information, apparently up to date, the like of which in a single volume it would be difficult to find elsewhere. Inasmuch as it is issued by Dr. A. Newsholme, author of "Elementary Vital Statistics," and principal medical officer to the Local Government Board, the accuracy of the statements may be taken for granted. In most civilised countries decline of the birth-rate is undoubtedly taking place, the relation of which to "natural increase of population" is discussed in the text. In the author's judgment this decline can hardly be attributed to postponement or avoidance of marriage. When women of equal age in a given country are compared with women of the same country 20 years later, a great decline of fertility is observed in many parts of the world. But volitional limitation of families appears to be the predominant cause of decline in the birth-rate, both here and abroad. The limitation of families is known to be operative in many countries; and this, rather than an increase of sterility, of which there is no evidence, may be regarded as the governing factor in the diminishing birth-rate. From all the facts available the conclusion seems inevitable that this calamity is chiefly due to causes within human control. The same conclusion is suggested by the fact that in countries like Ireland, where "preventive measures" are forbidden on religious grounds, the corrected birth-rate continues high.

To the general reader the chief value of this pamphlet will be for reference. In the brief notice for which alone we have space it is impossible even to touch upon many of the topics handled in the text, for a fuller discussion whereof the pamphlet itself must be consulted.

LIBRARY TABLE.

Fathers of Men. A Book for Boys. By E. W. HORNUNG. London: Smith, Elder, and Co. Price 6*s.*—A book for boys, about a school, makes its appeal for the most part to an uncritical audience, who may be ready enough to detect small slips in detail, but who will forgive such errors in return for something gallant in heroes, dexterous in athletes, or heinous in villains. Those of us who are no longer boys are inclined, if we take up such books, to be less easy in our judgment; we do not detect errors in slang or the improbabilities of feats on cricket ground or running path, but we are quick to compare our own recollections, possibly fading, with the printed record of young Jack Harkaway; and when we do so we generally find Jack Harkaway's experiences to be not our own, though we may not be prepared to assert that such things do not happen nowadays and in inferior places to the paramount school which had the privilege of educating ourselves.

This is, perhaps, only a long-winded way of saying that a book for boys, about a school, as a rule, is a poor book, succeeding mainly through the amiability of its readers. A poor book on these lines should be an easy one to write, and we think that this is the case, for it is written by the score. But a good and serious book upon school-life, by which we mean to imply one that is written with accurate knowledge, with the intention to create the due atmosphere, and with a sense of the part played in modern English history by the English public school, is a rare work; to write it is an exploit which so far has been accomplished only two or three times. The author has to be old as well as young, just and also enthusiastic, quite sensible but with a proper sympathy for silliness, a censor of manners and morals, and yet a hero-worshipper. Mr. Hornung has the necessary and rare qualifications thus set out, and he has written a book of this serious order about Uppingham School. It is his challenging title, "Fathers of Men," which induces us to notice it in the columns of a medical journal. That the boy is the father to the man is a thesis of medical interest wherever the perpetual question of the value of public schools is in debate, for if there is one thing we are asked more persistently to believe than another it is that the public school environment annuls individual character and turns out young persons all in one mould, knowing exactly with what conventional codes to conform and in what collars and neckties to appear by morning, noon, or night, but otherwise ill-prepared for the life that lies ahead of them. It is suggested by one of the most sympathetic creations in Mr. Hornung's book that this view is nonsensical. Mr. Hornung writes impersonally, but the teaching of his story as a whole leads us to think that he, like his excellent Heriot, believes essential character to be largely independent of surroundings. Such a belief, which we are ready to share, forms a fine testimonial to the much censored public school system, and many a medical man, asked by anxious parents to advise as to the training of their children, will be glad to find the arguments for a reassuring belief in the public school system between the covers of a thoroughly good book.

Mr. Hornung has written a minute account of Uppingham School during the "eighties" under its celebrated head, Edward Thring. Of Thring he gives a remarkable sketch, always sympathetic though now and again critical, while behind all his allusions to that forceful man we see an enthusiasm for his high ideals and aspirations. Certainly under Thring's *régime* boys did not tend to become all of one pattern, for while his ideas of discipline were strict his respect for individuality, even of the individuality of the fourth-form boy, was very real. The message of Mr. Hornung's book is that great good comes of such a reasonable attitude towards boys, whose "young barbarity" will be found to be much on the surface by anyone taking the trouble to scratch below it. A combination of perfectly simple writing with sound psychological thinking makes "Fathers of Men" a remarkable book, and one which the many grandfathers of men will enjoy. It goes without saying that the author of "Peccavi" has planned his story well, and that the creator of Raffles narrates its more salient episodes with spirit and humour.

Leitfaden der Röntgen-Verfahrens. By F. DESSAUER and Dr. B. WIESNER. Fourth edition. Leipzic: Otto Nemnich. 1911. Pp. 366. Price 12 marks.—This is a practical text-book of Roentgen technique written by the well-known physicist and engineer of the Veifa works, in collaboration with a number of specialists, among whom the best known in this country are Holzknecht, of Vienna, and Hoffa, of Berlin. It will be familiar to English students, for a translation of the first edition was published by Messrs. Funk and Wagnalls in 1904. The present edition is much enlarged. The early part, comprising more than half the book, is devoted to the physics and the technique of the Roentgen rays. These are both treated of in a satisfactory manner. The technical directions are particularly good—those, for instance, for the care of the focus tubes, which impress the necessity of keeping them clean and free from moisture, of keeping a selection of tubes of different degrees of hardness, and of softening them once for all and thoroughly when it is absolutely necessary. No better estimate of the comparative merits of the different machines—the Coil, the Grissonator, the Snook, and the Blitz apparatus—can be found anywhere than in the chapter on Roentgen technique by Dessauer himself. Indeed, one of the great merits of the book is the fair and liberal way in which apparatus by different makers is discussed. The chapter on surgical diagnosis is written by Professor Hoffa, and that on the Roentgen therapy by Holzknecht. The sixth chapter dealing with orthodiagraphy and ortho-photography (ortho-skiagraphy would be a better term) is from the pen of Professor Hoffmann, of Düsseldorf. Holzknecht is responsible for the section on Roentgen Diagnosis in Internal Medicine. He insists on the advantages of his hanging screen, supported from the ceiling by balance weights. It is to be regretted that this is not more often used in England, since it is the only method by which Roentgen palpation—i.e., palpation of the abdominal organs under the Roentgen light—can be satisfactorily carried out. This palpation may be effected with complete safety to the operator by the use of Holzknecht's "Distinctor," or, what is equally convenient, a long wooden spoon. In the Roentgen examination of the stomach and intestines half the benefit is lost if the abdomen is not palpated in this way, by the hand, a wooden instrument, or the pressure of the screen. One of the most instructive chapters is also by Holzknecht, and gives the tracings of the screen examination in medical cases. These contain 22 diagrams of the Roentgen diagnosis in diseases of the chest and abdomen, all of which are of the greatest interest. The book is what it professes to be—a guide to Roentgen technique, containing what a student really ought to know, and not too overburdened with detail. It would be of advantage if this fourth edition could find an English translator, or perhaps better still an imitator, who could write with the zeal and knowledge displayed in this work.

The Life of Dr. Arthur Jackson of Manchuria. By the Rev. ALFRED J. COSTAIN, M.A. London, New York, and Toronto: Hodder and Stoughton. 1911. Pp. 187. Price 2*s.* net.—This is a simply and sympathetically written record of the life and death of a medical man who laid down his life at the early age of 26 years in pursuance of his duty of ministering to the sick. The records of our profession contain, we say it with pride, many similar instances of devotion, but Jackson's death occurred in dramatic circumstances which are wanting in those instances of medical men who are fatally infected in the course of everyday practice. He died from plague far away from his home at the Chinese railway station at Mukden and he was ministering not to his own kith and kin, but to Chinese coolies. His duty, for which he had volunteered, was to examine Chinese coolies who were coming down to Mukden from Northern Manchuria, and to stop those who were plague-infected, as most of them were. The Manchurian outbreak of plague during the winter of 1910–11, though comparatively small in extent, was very virulent, and all the more so in that the cases were almost all of the pneumonic type.[1] Jackson had only been in Mukden for ten weeks. He had come out as a medical missionary of the Scottish Presbyterian Mission, and his nominal sphere of work was the mission hospital. But when plague, following the line of the railway, crept down to Mukden it was evident that something must be done to stay its spread to Peking. Hence the intercepting post at the Chinese railway station and Jackson's appointment as medical officer of the intercepting organisation. In spite of every precaution, for he was too sensible to throw his life away by carelessness, Jackson became infected. He had arrived at Mukden on Nov. 14th, 1910; on Jan. 25th, 1911, he was dead. In our obituary notice[2] are recorded some details of the valuable work done by him, even in that short period, as well as a notable and pathetic tribute which was paid to him at his funeral by the Viceroy of Manchuria. Mr. Costain's book—while giving this and other interesting information—will also serve as a memorial of a noble life, untimely cut off, and one of which his professional brethren, his school (Merchant Taylors, Crosby), his university (Cambridge), and his final medical school (Liverpool), may well be proud.

The Anopheline Mosquito. Some Facts and Information for Use in Schools. By R. C. DAUGLISH. With an Introduction by J. W. W. STEPHENS, M.D. Cantab., Liverpool School of Tropical Medicine. London: John Murray. 1911. Pp. 28. Illustrated. Price 6*d.* net.—This little book, which is dedicated to "the Children of the Empire," is instructive and interesting. Mrs. Dauglish wrote her story of the anopheline mosquito for a society formed in Barberton, in the Transvaal, to fight malarial fevers, the society being known as the Barberton Anti-malarial Association. The facts set forth are simple and clearly expressed, and the lay reader will find carefully explained to him how to keep himself free from "fever" or "ague." The story of Ismailia is an example of what modern research can attain to. The book should be of particular use in the schools in those countries where anopheline mosquitoes and malaria are found, and to adults visiting such places.

Tuberculosis: A Plain Statement of Facts regarding the Disease. Prepared especially for Farmers by the International Commission on the Control of Bovine Tuberculosis. Published by the Government Printing Bureau, Ottawa, Canada. 1911.—This excellent brochure of 30 pages combines in a short space a number of most telling facts clearly illustrating the untrustworthiness of an opinion upon the presence or absence of tuberculosis in cattle based on external appearances only. The author, Dr. J. G. Rutherford, C.M.G., F.R.C.V.S., the Veterinary Director-General for Canada, thus endeavours again to bring before farmers and others interested in cattle the dangers of tuberculosis, and the value of the application of the tuberculin test for stamping the disease out of a herd. He deals with the subject in simple language, and increases popular interest by a series of excellently reproduced photographs. The brochure can be obtained by medical men upon application to the Government Printing Office, Ottawa.

Essentials of Surface Anatomy. By CHARLES R. WHITTAKER, F.R.C.S. Edin., F.R.S.E., Senior Demonstrator of Anatomy, Surgeons' Hall, Edinburgh. Second edition, revised and enlarged. London: J. and A. Churchill. 1912. Pp. 59 and 12 plates, comprising 20 figures. Price 3*s.* 6*d.* net.—

[1] THE LANCET, April 29th, 1911, p. 1152.
[2] THE LANCET, March 11th, 1911, p. 707.

Mr. Whittaker is to be congratulated upon the appearance of the second edition of this little work, for the publication of a new issue has given him the opportunity for making several improvements, the most obvious of which is the inclusion of some outline drawings. These are for the most part not very ambitious pieces of work, but they have the merit of simplicity, and all answer their purpose well. The book gives in simple form the most important surface markings and landmarks of the human body, and as an epitome of these it may well fill the same sphere of utility that its former edition has so successfully occupied. Perhaps it would be well to consider if, with an increase of this sphere of utility, it would not be advisable to include, at any rate within brackets, the nomenclature laid down by the Basle agreement. For anything save a local reputation it seems likely that such a step would be essential.

A Naturalist on Desert Islands. By PERCY R. LOWE, B.A., M.B. Cantab. London: Witherby and Co. 1911. Pp. 300. Price 7*s.* 6*d.*—For the grown man who remembers his "Robinson Crusoe" and his "Coral Island," the subject of desert islands is one of perennial interest, and Dr. Lowe's description of islands which, if not exactly desert, are still in a very primitive condition, will take many readers back to the days of their youth. The islands in question are the two Swan islands, Blanquilla and the Hermanos. The first two are specks of coral situated in lat. 17° 25′ N., and long. 83° 56′ W., or, roughly speaking, 98 miles north of Cape Patook in Honduras. Blanquilla belongs to Venezuela and is close to the Hermanos, which belong to the same power. Their position is roughly lat. 12° N. and long. 64° 30′ W. Dr. Lowe visited them recently in company with Sir Frederick Johnstone and Lady Wilton his wife, and this book gives an account of the geological and zoological features of the islands, which are of quite disproportionate interest as compared with the size and commercial or political importance of these atoms of land. Swan Island (there are two, but they are only 400 yards apart, and the second one is only about one mile long by half a mile wide, so that we may speak of them as one) is practically a "buoy" marking the southern edge of Bartlett's Deep, a depression in the sea bottom of some 18,000 to 20,000 feet in depth. The only inhabitants are a "Mr. A.," his father, mother, brother, and a few negro servants. The island is apparently quite oceanic—i.e., it has never had any dry land communication with the mainland, and therefore its flora and fauna offer many problems as to how they arrived at their present habitation, and Dr. Lowe's speculations on these problems are by no means the least interesting portion of his book. Blanquilla and the Hermanos come in a different category and form part of the long chain of islets running along the north coast of Venezuela. Blanquilla is inhabited by one family, one member of which lives apart by himself; the Hermanos islands are given up to birds, whose tameness was in no way shocking to Dr. Lowe as that of the birds of a similar island was to Alexander Selkirk, but, on the contrary, of extreme interest. He expresses a hope that among the solitudes of these islands there may still be found examples of the apparently extinct race of petrels, oestrelata, which used to inhabit Jamaica. Anyone who cares for strange forms of animal life cannot do better than consult Dr. Lowe's charmingly written book.

MISCELLANEOUS VOLUMES.

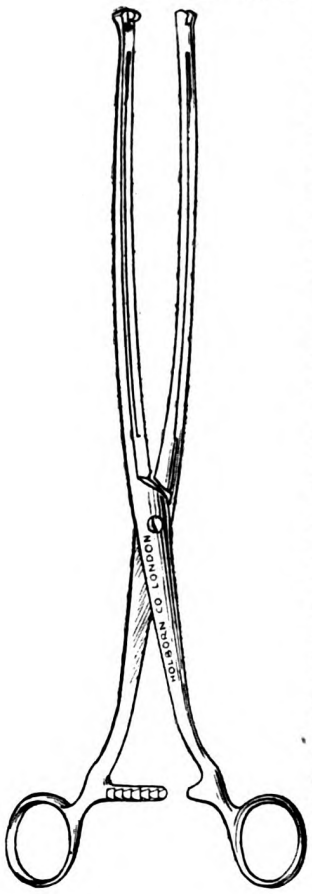
THE National Insurance Act is giving everybody much to think about, judging from the great output of books explaining it. *The Alphabet of the National Insurance Act, 1911*, by Mr. C. G. Moran, Barrister-at-Law (London: Methuen and Co. Limited. Price 1*s.* net), arranges the contents of the Act in dictionary form, so that the reader can at once put his finger on any particular point concerning which he may desire information. The idea is certainly a good one. The book is merely an alphabetical analysis of what the Act really provides, not in any sense an argument concerning its merits or defects.——In these days medicine touches on so many departments of life that there is probably no information, however technical, which the medical man may not at some time or other find useful, and the way in which our clothes are washed is certainly no exception to this statement. *The Washhouse and All About It*, edited by C. F. TOWNSEND, F.C.S. (London: The Power Laundry. 1911. Price 1*s.* net), deals with an important department in the cleansing of soiled clothing. It contains a general description of the washing process, and includes information as to the best way of removing stains, with comments on the use of chemicals, starch, bleaching processes, and so forth.——*The Modern Culture of Sweet Peas* (London: The Cable Printing and Publishing Company. Price 1*s.*) is a very practical little book by Mr. Thomas Stevenson, an authority on the subject. The book is already known to many, and its re-issue at a third of the original price will give to it the wider circulation which it deserves.——"Peeps at Industries" is the excellent idea of a series of books to be issued to give information about the great industries of the world, and the first of the series is on sugar. (*Sugar.* By EDITH A. BROWNE. London: Adam and Charles Black. 1911. Price 1*s.* 6*d.* net.) The author adopts a free conversational style and tells her interesting story quite well. We have read the accounts of cane and beet cultivation, and the manufacture and finishing of the sugar for the markets, with great pleasure. The industry, moreover, has many historic features.——The question whether beet cultivation, with the view of making sugar therefrom, can be made to pay in England is very fully discussed in *Sugar Beet, Some Facts and Some Illusions*, by Home Counties (J. W. ROBERTSON-SCOTT). (London: Horace Cox. 1911. Price 6*s.*). The book is a valuable contribution to the subject. After careful inquiry in a great many directions the writer concludes that (1) "there is good reason to urge that those who have suitable land in the vicinity of a proposed factory should make the experiment of beet growing for three or five years; and that they should be supported by landlords and by local opinion"; (2) "if the best price for roots with a reasonable sugar percentage is given, a price it should be apparently within the power of properly planned and properly managed factories to pay, and the new crop is grown with the intelligence, business acumen, and attention to detail which distinguish our agriculturists—proper regard being had to Continental experience—beet growing should prove as remunerative as it is found to be in Holland by farmers who are not factory shareholders."——There are now quite a number of books dealing with the practical side of milk production. A good guide to the testing of milk by chemical methods has recently been published under the title of *Milk Testing: A Simple Practical Handbook for Milk Producers and Distributors.* (London: The *Dairy World* Office, price 1*s.*) The author, Mr. C. W. WALKER TISDALE, F.C.S., shows an intimate acquaintance with his subject, and the tests he describes should be clear to the dairy farmer and his assistants. The list of tests is, moreover, a very comprehensive one.——In *Milk and Cream Testing*, by G. SUTHERLAND THOMSON, F.R.S. Edin. (London: Crosby Lockwood and Son, 1911, price 4*s.* 6*d.* net), we find a book designed for reference in the school, farm, and factory. The directions and tests given are obviously the outcome of a wide practical experience, while the arts of making butter and cheese are ably discussed with due regard to the special modern scientific developments bearing upon this important industry.——The University

Press of Aberdeen has recently published a subject catalogue containing the titles of the books in the Phillips Library of Pharmacology and Therapeutics, Marischal College, which was founded in memory of the late Dr. C. D. F. Phillips by his widow. Dr. Phillips contributed several works on Materia Medica and Therapeutics, and his library shows what a vast source of reference on this and cognate subjects he kept by him.——Dr. J. Ewing Mears is to be commended for his effort to spread broadcast a knowledge of what is probably the greatest object lesson the world has had of the power of intelligent and scientific sanitation to abolish deadly diseases that have for centuries held certain tropical countries in their grasp. Of countries so oppressed, perhaps the Isthmus of Panama was the very worst; yet so important was it to world progress that thousands of lives have been lost there in futile attempts to utilise it for the purposes of commerce. In the *Triumph of American Medicine in the Construction of the Panama Canal* (Philadelphia: W. J. Dornan. 1911. Pp. 26) Dr. Mears traces the transformation of the "canal zone"—a belt of territory containing 322 square miles, extending 5 miles wide on each side of the Panama Canal, extending from the Atlantic to the Pacific—from a pestilence-ridden area, reducing the death-rate of all white folk who went there from 70 per cent. to under 1 per cent. He details the measures and precautions taken in the achievement of this result, which certainly fulfil the definition of genius as "an infinite capacity for taking pains." It is not so much superior knowledge as superior powers of organisation that has rendered possible this remarkable achievement of Colonel W. C. Gorgas, of the Medical Corps of the United States Army.——In a *Manual of Heraldry* (London: T. Werner Laurie. Pp. 291. Price 6*s*. net) Mr. Gale Pedrick traces the rise, progress, and decay of this ancient science, without some knowledge of which, he truly says, it is absolutely impossible for anyone to understand and appreciate the associations and even the beauty of much poetry, art, architecture, or literature. The beauties of symbolism are being too much lost sight of in this realistic age. In this book the precursors of heraldry are described, the authorities of British arms explored, the various charges and armorial instances are historically and symbolically discussed, the influence of heraldry upon art and architecture, archæology and genealogy, as well as upon literature and poetry (particularly that of Scott), is expounded, and finally the author proposes a reform of heraldry—whose spirit from an archæological and artistic standpoint is always fresh, though its ancient exercise is dead and incapable of resuscitation—by measures designed to accommodate it honourably to modern conditions. The illustrations of coronets, ordinaries, tinctures, differences, and so forth, are facsimiles of those contained in a "Pocket Herald" and "Gentleman's Companion," published by Richard Barry, of Bristol, "as the Act directs," on August 1st, 1810.——The fourth (revised) edition of Hassam's *Arabic Self Taught* (*Syrian*) (London: E. Marlborough and Co. 1911. Pp. 128. Price, paper, 2*s*.; cloth, 2*s*. 6*d*.) has been practically rewritten by the Rev. N. Odeh, and much entirely new matter, including an outline of the grammar, has been added. The transliteration used has been carefully devised to give the phonetic pronunciation of Arabic in accordance with the scheme adopted by the Congress of Orientalists, and has been simplified to the last degree.

Messrs. John Ouseley, Limited, of 6, Fleet-lane, Farringdon-street, E.C., ask us to state that *The Blood and its Third Anatomical Element*, by A. BÉCHAMP, translated by Dr. MONTAGUE R. LEVERSON, which was reviewed in THE LANCET of Jan. 27th, p. 235, is published by them in this country at 6*s*. net.

New Inventions.

A NEW STOMACH CLAMP.

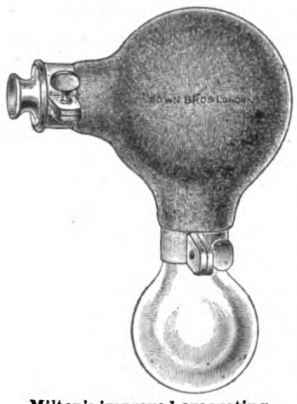


THE accompanying figure illustrates a stomach clamp recently made for me by the Holborn Surgical Instrument Company, Holborn-circus, London, E.C. The blades may be had either straight or curved. It has been a well-recognised difficulty to obtain a clamp possessing length and rigidity with strength sufficient to effectually retain a grasp on the stomach without unduly crushing it. This instrument has the desired spring, and with the end locking arrangement there is no possibility for the blades to side-slip. The fenestræ permit, if desired, the insertion of sutures to prevent hæmorrhage, while at the same time they assist in retaining the grip upon the stomach wall after division. If the slot be not desired, rubber tubes may be placed over the blades, but this is not recommended as the forceps possess the necessary rigidity and safe grasping power when used naked. If covered by rubber the blades must be locked much too tightly to retain a hold without risk to the tissues grasped.

ALEX. MACLENNAN,
M.B., C.M. Glasg.
Glasgow.

A NEW EVACUATOR FOR LITHOLAPAXY.

IN THE LANCET of Jan. 20th Mr. John Pardoe draws attention under this title to the fact that many of the older forms of evacuators for litholapaxy are made with their metal collars permanently attached to them, and he describes an evacuator of the Bigelow type in which the glass bulb is removeable from the bottle.



Milton's improved evacuating apparatus.

Messrs. Down Bros., Limited, point out that Mr. Milton's evacuators have been made with both the mounts removeable for many years past, and were first described in their catalogue in the year 1900, and the illustration appended has appeared in their catalogue since the year 1906. That being the case, it has naturally drawn attention to the matter, and they have been frequently called upon to supply, and have made, Bigelow's and most other models of evacuators with removeable screw collars made on the same principle as those shown in the accompanying illustration.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 10, 1912.

The National Insurance Act.

As we foreshadowed in our last issue the conference which the National Insurance Commissioners proposed to hold with representatives of medical interests on Feb. 2nd came to nothing. Finding their invitation declined by such important bodies as the General Medical Council, the Royal College of Physicians of London, the Royal College of Surgeons of Edinburgh, the Society of Apothecaries, and the Council of the British Medical Association, and being threatened with refusal from other bodies whose answers they awaited, the Commissioners decided at the last moment to postpone the conference. The reasons given for not accepting the invitation of the Commissioners varied in different quarters, but the feeling behind the replies was clearly much the same everywhere. The strongest and the most general objection to attending the conference was that it had been sprung upon the bodies concerned without giving them time either to consult their constituencies or to confer together. In support of this suddenness we presume that the Commissioners would quote Section 58 of the Act, which instructs them, "As soon as may be after the passing of the Act" to appoint an Advisory Committee for the purpose of making and altering regulations under the Act. If the object of the conference had been confined to obtaining the help of the medical profession in forming this Advisory Committee (which must contain "duly qualified medical practitioners who have personal experience of general practice"), and if the invitations had been given with proper notice and due discrimination, the various bodies might have replied with less unanimity. For the formation of the Advisory Committee is the necessary prelude to the issue of the Regulations. But even if the Commissioners had displayed both tact and knowledge of the medical profession, it is very likely that the attempt to secure a conference with representative medical bodies would have failed, so strong is the feeling that no regulations whatever can shape the medical provisions in the existing Act into an acceptable form.

We know that this view is not held universally, and we publish this week the first of a short series of articles by Dr. W. A. BREND upon the position of the medical profession under the Act, which are designed to persuade the profession that a scrutiny of the parts of the Act affecting the medical profession will show the practitioners to be in a stronger position than is usually supposed. We choose this time for publishing Dr. BREND'S articles because there has been during this past week a remarkable unanimity in certain political papers in misrepresenting the point of view of those medical men who are opposed to the Act, while we are sure that our readers are as willing to hear both sides of any question as we are desirous of presenting those sides. The method employed by politicians has been to suggest that our opposition to the measure is purely the outcome of Tory bias or greedy terror, and it is endeavoured to prove this suggestion by demonstrating that as within the covers of the Act everything that is wanted by any fair-minded medical man can be obtained, no medical man can oppose the Act and be fair-minded. We invite our readers to study Dr. BREND'S articles and form their own conclusions. It is on the principle of *audi alteram partem* that we print this "Examination of the Medical Provisions of the National Insurance Act." It will be obvious to all who have followed the previous leading articles in THE LANCET that Dr. BREND is not in agreement with ourselves as to the main issues, but it is always well to clarify our ideas by a critical study of the strongest case that can be made out for the other side by one who can speak as an expert; and Dr. BREND has clearly studied the Act very closely as a barrister, while as a medical man he can appreciate the force of medical arguments. Our lay critics have not these advantages.

The result of the breakdown of the conference with the Commissioners is surely to show that, at any rate, delay must be granted before the working of the Act commences; the most favourable view of the medical provisions in the Act that can be taken by any partisan seems to us to point the same way. During the week an exposition of the National Insurance Act has appeared which will surely be studied with the greatest possible attention by many of our readers, and they will note in the preface, contributed by Mr. LLOYD GEORGE, that the Chancellor anticipates difficulties in the working of the Act, although he does not go so far as to admit, as Sir JOHN SIMON, the Solicitor-General, has already done, the certainty that amendments will be required. The description in this volume [1] of the position in which the medical profession will be placed by the working of the Act has been very carefully done, but the thing that stands most clearly out therefrom is summed up in the words of the authors: "It is impossible to forecast what the ultimate effect of the Act will be on the medical practitioners ....." That incomplete sentence of an excellent work, carefully written and admirably edited, forms a powerful argument for insistence upon delay in the working of the Act. The medical profession was not consulted before the original Bill appeared. During its transformation into the very different Act that it is, the representations of the medical profession were rewarded by little tangible improvement. The medical profession has come to a fairly unanimous opinion that under the existing medical provisions they will not obtain fair treatment—a statement which is fully borne out by the pledges given by many thousands of medical men, and which will receive endorsement at the forthcoming

meeting of Representatives of the British Medical Association. There is no reason why they should be forced into working a measure concerning which they have never been duly consulted; and there is no justice or sense in representing their opposition to the measure as political. What is required now is an assurance that delay in the working of the Act will be granted; failing this the outcome may be very sad.

The Panama Canal and the Spread of Exotic Disease.

THE axiom that "disease follows trade" stands on a firm basis, past experience having shown that many maladies, particularly those classed as exotic, travel commonly along commercial highways by land and sea. In the olden days of trade caravans and sailing ships the spread of these infections was comparatively slow, but with the introduction of railways and steamships the diffusion of disease has become more rapid. The linking of the Atlantic and the Pacific Oceans by the ship canal now being cut through the Isthmus of Panama has therefore become of the highest importance to the whole world. We have described in our columns the sanitary procedure at the immense works,[1] and it is this which enables the Government of the United States to anticipate that the canal will be opened in about two years' time. The canal will create an entirely new situation, both in commerce and international sanitation, for it will place in communication ports which have hitherto had no direct trade with each other. For instance, the numerous ports situated on the western shores of South America will then have direct communication with the so-called Gulf ports in the south-east of the United States, and steamships from Eastern America will be able to sail across the Pacific to Japan, China, and India. Fears have already been expressed by epidemiologists that these altered geographical conditions may facilitate the spread of infection of such diseases as plague and yellow fever. One aspect of this subject has been dealt with recently in the *New Orleans Medical and Surgical Journal* by Dr. HOWARD D. KING, who in a vigorous article sounds the alarm, and warns New Orleans of the risk it will run on the opening of the Panama Canal from plague imported from the ports situated on the western shores of South America in the republics of Colombia, Ecuador, Peru, and Chili. In these States plague has been prevalent for some years and is in places increasing in amount, accompanied by a concurrent epizootic of plague among rats. At present there is no direct communication by ships between these ports and those like New Orleans, situated on the Gulf of Mexico; but when the canal is opened they will be within a few days' sail of each other.

None of the four States above mentioned possesses a sanitary administration worthy of the name, nor is there any trustworthy certification or record kept of the causes of death. Moreover, with plague, as with other infectious diseases, a policy of concealment is commonly adopted, and the bulk of this population is entirely apathetic in the matter of domestic and public sanitation. The measures hitherto employed to check the spread of plague have been inadequate, and such as they are they have been inefficiently carried out. In the circumstances there seems little prospect that these infected States will lend much assistance in preventing the exportation of human and rat plague, which must inevitably follow when the canal is opened for traffic and shipping communications are greatly increased. There are many fine harbours on the west coast of South America, and as soon as the new trade route is ready the vast resources of the interior of this part of the country as yet unexploited will be rapidly developed, with consequent great augmentation in the number of steamships calling at the ports. But the ports in the west of South America are not alone in their neglect of proper precautions against plague, for it appears from Dr. KING'S statements that New Orleans, and presumably other Gulf ports, are equally unready to deal with the disease. In New Orleans, with a population of over 370,000, are a number of recently arrived Italians of the poorer class, and also many negroes, whose mode of living often violates every modern sanitary requirement. Close to the river front, and within a stone's throw of the ships berthed alongside the old wooden wharves, are to be found warehouses, freight depôts, grain elevators, cold storage plants, factories of various kinds, along with stables and other buildings, all of which are overrun with vast hordes of rats. In the vicinity are situated working-class dwellings, some of them of a wretched description and notoriously lacking in most sanitary requisites. Men and animals, Dr. KING says, are housed in close proximity, and courts and backyards are littered with rubbish and household refuse. Bred for many years amidst a population opposed to sanitation rather than indifferent to the inconvenience of its institution, the rat lives and multiplies in most intimate association with the people; and families of rats occupy the same room with the human tenants. Foodstuffs are stored in the living apartments, thus affording a plentiful and easily accessible supply for the increasing rodent population. We can hardly conceive a combination of circumstances more favourable to the spread of plague. If infected rats, brought by steamships from infected ports, should land and mingle with the local rodents it would be almost an impossibility to prevent a serious epidemic of plague arising in New Orleans, and with probable extension of the outbreak to the valley of the Mississippi and even to the very heart of the United States. It is earnestly to be hoped that the municipality of New Orleans will take Dr. KING'S warning seriously to heart, and that in the short intervening period before the opening of the canal the necessary steps will be taken to remedy the existing insanitary conditions and especially to carry out a war of extermination against rats.

This is not the first warning that New Orleans has received of the plague danger, for two years ago, Surgeon J. H. WHITE, of the United States Public Health and Marine Hospital Service, drew attention to the grave insanitary conditions in the city and to the probable arrival of the infection from not far distant affected ports. As long ago as 1903 Sir PATRICK MANSON approached the subject from another aspect, that of the possible conveyance of yellow

[1] THE LANCET, vol. i., 1905, pp. 1530, 1597, 1726.

fever virus, in the form of infective stegomyiæ, on board ship through the canal from the well-known endemic area of the disease on the east of South and Central America, into the Pacific, and thence to the ports of India, China, or Japan. His views, which were fully set out in a paper [2] which he read before the Epidemiological Society in London, caused at the time some uneasiness and received the support of other eminent epidemiologists. Although a committee was appointed to draw up recommendations to meet the anticipated danger, and to make representations to our own and the United States Governments, we fear that ultimately the matter was allowed to drop. At the present time an International Sanitary Conference is sitting in Paris to discuss proposals for the purpose of amending the existing convention agreed upon by the Powers in 1903 with the object of preventing the spread of cholera, plague, and yellow fever. Official delegates from the United States and from nearly all the republics of South America, as well as from some Asiatic countries, have attended at Paris with the representatives of the Powers of Europe to discuss the best means for protecting all parts of the globe against the infections of these three exotic diseases. In the circumstances we think it is extremely probable that the attention of the delegates will be directed to the changed conditions which will be brought about by the completion of the Panama Canal and to the increased facilities which will be afforded for the conveyance of certain diseases along this new trade route. The matter will, no doubt, receive the most careful consideration, and the result will in all probability be included in the new International Sanitary Convention which will be submitted to the Powers for signature.

We may here refer to the sending of Major S. P. JAMES, I.M.S., on a deputation to study yellow fever in the endemic area in order to advise the Indian Government in regard to preventive measures. It is worthy of mention that under the direction of the medical experts appointed by the Isthmian Canal Commission a very great deal has been done to remove from that area the unwholesome conditions which for many years made the canal zone notorious for its unhealthiness.[3] At the present moment malaria and other tropical diseases, including yellow fever, have been controlled to a very large extent, and the region around the canal may now be said to be comparatively healthy for Europeans. Local efforts such as these have far-reaching effects, and while we admit the great benefits which the provisions of an International Sanitary Convention will confer upon those who become parties to it, we are of opinion that much can be done locally by individual efforts. Prophylaxis, like charity, should begin at home, and owners and occupiers, in addition to the local and central health authorities, have their parts to perform in trying to secure wholesome conditions of living for all by scrupulous cleanliness of persons and houses, protection of food- and water-supplies, the provision of proper drainage, excrement disposal and scavenging, and particularly the waging of war continually against dangerous insects and vermin of all kinds, with removal of every condition likely to favour their multiplication. Such measures, if properly carried out, not only assist in preventing the spread of exotic disease, but add much to the general health and comfort of the people; and perhaps they may, in their place, be regarded as being, on the whole, of more general utility than the rigid enforcement of restrictive quarantine, or the needless disinfection of articles of merchandise.

[2] The Relation of the Panama Canal to the Introduction of Yellow Fever into Asia, read on Feb. 25th, 1903, before the Epidemiological Society in London. See THE LANCET, March 7th, 1903, p. 658.

Prehistoric Bones.

AT the present time our knowledge of prehistoric man is expanding rapidly. During the last few months several works have appeared in England which aim at giving the general reader a knowledge of this subject. Taking them in the order in which they have appeared, these are "Ancient Types of Man," by Professor A. KEITH, which we review in another column; "Ancient Hunters," by Professor SOLLAS; and "Prehistoric Man," by Dr. W. L. H. DUCKWORTH. We are glad to see that English anthropologists are awakening to the resources of their country, for of late years our eyes have been centred on France, believing that the history of fossil man could only be deciphered in that country or in the neighbouring parts of Central Europe. As matters now stand the appearances are in favour of England again taking her place in the van—a place which she held throughout the opening half of last century. The foundation of our knowledge of prehistoric man was laid by JOHN FRERE, who in 1797 discovered at Hoxne, on the border-line between Norfolk and Suffolk, well-worked flint implements of a primitive type under a deep layer of brick earth. Brick earth is regarded at the present time as a deposit left by the floods which followed *one* of the glacial periods. In such deposits are found remains of the mammoth, of the woolly rhinoceros, and many extinct and living forms of animals. We have now come to recognise that these flints found and described so long ago by JOHN FRERE belong to what may be called the Acheulean civilisation, because at St. Acheul, in the valley of the Somme, North-West France, these implements occur so abundantly. Now the French experts have shown that such implements were used by the ancient inhabitants of Europe who preceded Neanderthal man, whose flints belong to a later and really lower civilisation, known as the Mousterian. We naturally infer from these facts that there must have been a race of men living in England long before Neanderthal man, with his massive face, beetle-brows, and acromegalic characters, appeared in France.

It is in this connexion that the human skeleton discovered recently by Mr. J. REID MOIR near Ipswich becomes of importance and interest. Over the skeleton thus found there was only a layer of boulder clay four feet in thickness. Fortunately there were experts at hand to see the remains exhumed and to examine minutely the surrounding and overlying strata, and they are confident that the boulder clay was unbroken and undisturbed, a condition which precludes the possibility of a burial at this spot—at least since the boulder clay was laid down, after the great period of glaciation. We must therefore assume that the skeletal remains thus found are older

than the boulder clay, and we turn at once to see how this pre-boulder-clay man stands in relationship to the people who fashioned JOHN FRERE'S implements at Hoxne. Thanks to the labours of the British Association we have a very exact knowledge of this relationship. The Hoxne implements are much more recent than the boulder clay. Between the brick earth, under which these flint implements occur, and the boulder clay, there is found a series of strata, one of them containing remains of Arctic plants and a deeper one with temperate plants. If the boulder clay represents one period of glaciation and the Arctic plants another and much later cold period, then we see that between the time of the pre-boulder-clay man and that of the men of Hoxne there elapsed at least two glacial and one interglacial or temperate period. In the boulder clay and in the underlying glacial sands Mr. MOIR has found well-worked flints which may be regarded as the handiwork of the Ipswich race. He found worked flints at a much deeper or older horizon—namely, beneath the red-crag formation which marks the passage from the Tertiary to the Quarternary period—a point in time prior to the Glacial period. We have every reason, then, to anticipate the discovery of a pre-boulder-clay man, or, to use a common but an inexact term, pre-Glacial man. The skeletal remains thus discovered were examined by Professor KEITH. He found that all the characteristic features of the Neanderthal race were absent; the skeleton belonged to a tall man of the modern type. The brain capacity was comparatively low—namely, 1430 cubic centimetres (Neanderthal man had a capacity of 1600 cubic centimetres or more); the skull was rather flattened from above downwards, as is the case in Neanderthal man. The peculiar features of the skeleton lie in the bones of the leg. There is no crest or shin to the tibia; it is of a form not yet seen in ancient or modern races.

Until the Ipswich discovery was made—we are presuming that those concerned will be able to prove the geological age—the earliest human remains found in England were those from the 90-foot terrace of the Thames Valley, near Galley Hill, Kent.[1] The terrace is a remnant of the bed of the Thames; since it was laid down the river has excavated the wide valley below the level of that terrace. In the case of the Galley Hill skeleton there could be no question of burial; it lay beneath 8 feet of stratified sand and gravel. If the remains had been of the Neanderthal type they would have been at once accepted as genuine, but because they represented the modern type they were rejected by the majority of anthropologists. Yet the flints which are found in the upper terrace belong to a stage of evolution long prior to the Mousterian period which marks Neanderthal culture; they are even older than the Hoxne flints. We have again irrefutable evidence here that the modern type of man was in existence long before the Neanderthal man became extinct. The evolution of the modern type of man has to be sought for in a pre-Glacial period, or at an even earlier date in the earth's history. It will be thus seen that England again becomes a leading centre for tracing the later stages in the evolution of man. The geological formations in East Anglia are the most likely of any in Europe to yield convincing evidence. This is a sort of inquiry which medical men more than any are qualified to take a part in, for it is research which requires the greatest patience and care. The import of any discovery of human remains depends entirely upon being able to assign a date to them. Without such evidence they are almost valueless. In burials belonging to periods such as the Saxon, Roman, Bronze, or Neolithic, means of dating may be found by remains of the civilisation found with or over the remains. But in reality we know very little of the people of England during those periods. As regards earlier periods, the evidence becomes almost wholly geological. The age of the stratum—as determined by its position, and by the animal and plant remains, and the kind of flints found in it; the condition of the overlying strata—must all be minutely examined and recorded. The contents of each stratum must be kept separate and preserved. Only those who have paid attention to this kind of investigation know the amount of valuable evidence which has been destroyed through ignorance. Only the other day a human skeleton was found at a depth of 16 feet in stratified gravel; it was destroyed because the farmer feared that a coroner's inquest might be held. It is natural, in such circumstances as the possibility of an inquest being required, to send for a medical man, and we hope that every medical man who may be thus called to the scene will remember that to the expert eye extraordinary historical evidence may be revealed.

Annotations.

"Ne quid nimis."

JANUARY AT HOME AND ABROAD.

THE weather continued mild and rainy in this country until January was about three weeks old, although the mildness was not so marked as during December and the rain was hardly so heavy and persistent. The change to a colder condition came rather suddenly, and the evil effect of the abrupt fall of temperature was considerably aggravated by the strength and penetrating power of the east and north-east winds which brought it about. During the earlier half of the month the thermometer continued to rise to about 50° F. with unusual frequency for the time of year, and frost, even on the grass, was seldom experienced at night. In the more northern parts of the kingdom there was a cold snap, with heavy snow, round about the 7th, and a good deal of snow accompanied the low temperature of the latter days of the month in the western and northern districts. Over the country generally the relative warmth of the nights, more than the warmth of the days, contributed to maintain the mean temperature of the month much above the ordinary level for January. This was especially true of the south and south-east of England. In the metropolitan area there were, until the 25th, only two or three nights with a minimum temperature (as recorded by the sheltered thermometer) below 32°, and in spite of the severe frosts of the end of the month the mean minimum temperature for the whole period was at least 2° above the average. Hampstead was the coldest of the metropolitan observing stations during the daytime, and Westminster the mildest, the former having a mean maximum temperature of 42·4° and the latter a mean of 45·1°. The nights, however, were slightly milder at

Hampstead than at the more outlying districts of Kew and Greenwich. The central district of Westminster was, as would have been expected, the mildest at night, its mean minimum temperature being 39°, or about 3° higher than at Kew and Greenwich. At Hampstead the thermometer remained below 40° during the whole 24 hours on eight days, while at Westminster a like occurrence was only recorded on four days and at Kew on five days. Very few days passed in any part of the kingdom without more or less rain (or snow). In London, regarded as a whole, there were as many as 22 days with a measurable quantity of rain, and the aggregate fall—nearly 3 inches at Kew and Greenwich, and between 3 and 4 inches at Westminster and Hampstead—was much in excess of the normal. A rainy month is occasionally a decidedly sunny one also, but it was not so in January. The sun was much in default both in the metropolis and in the country generally. In the City the total number of hours of bright sunshine was only five, and in Westminster nine; these figures are less than half the January average. The more outlying districts naturally had a better record, but even there the figure was only equal to about half of that usually recorded in January. Kew had 20 hours, Greenwich 27 hours, and Hampstead 29 hours. In London as a whole there were no less than 20 days without any bright sunshine. On the south coast of England there were also many days without sun, and the total for the month was only about 50 hours. At Paris, where also the weather was mostly mild and often wet, the sun only shone for 36 hours. In the southern countries of the continent the general state of the weather was hardly so bright as usual, although it was not cold for the time of the year. In Italy there was much rain, alternating with fair but not always bright weather, and on the Riviera the rain was unusually frequent. At Nice as many as 14 days brought more or less rain, and all of them were after the 10th. The total fall for the month was as much as 6·1 inches, or about twice as much as in London. In the matter of temperature, however, the Riviera had a great advantage over the warmest part of this country. Frost, except once or twice on the grass, was almost unknown, and the mean temperature of the afternoons exceeded 50°. At Nice it was 51°, and at some other places a little higher. At that resort, where the thermometer is apt to fall to a rather lower figure during the night than at most other places on the Riviera, the mean minimum was 40°, or about 4° above that in the London suburbs, and 1° above that at Westminster. On 22 days the sheltered thermometer rose to 50° or above, and on one (the 7th) touched 61°. In the south of Spain the weather was rarely at all cold, but rough winds and rain were experienced much more frequently, and at Malta and in Sicily the weather was also of an unsettled character, with somewhat sudden changes in temperature following a shift of the wind from the southward to the northward. Along the coast of Algeria a fairly uniform and high temperature was maintained, and although the wind was sometimes stormy and rain not very uncommon, the sun was never absent during long intervals. As a rule, the sheltered thermometer either rose to nearly 60° by the afternoon or went beyond it, and on a few occasions when the wind chanced to come from the southward it touched the 70° point. Switzerland and the central countries of Europe had somewhat varied weather, but taken as a whole it was not unseasonable. Severe frost was experienced during nearly half of the month, the cold being very intense in Germany and Austria. On many occasions the thermometer remained below 20° throughout the day, and fell to about 10° at night. Since February began, however, this record has been beaten in Germany, where the temperature has fallen below zero Fahrenheit.

ABDOMINAL PAIN AS A PREMONITORY SIGN OF DIABETIC COMA.

A CURIOUS premonitory symptom of diabetic coma is abdominal pain. Though mentioned in the text-books, it has not received much attention, and its pathogenesis is not well understood. It has received more attention in France than in this country. Jaccoud has described a "peritonitic form" of diabetic coma in which abdominal pain is the dominating symptom. Recently, at the Congress at Lyons, M. Marcel Labbé and M. Blum assigned a special importance to epigastric pain as a symptom. In the *Progrès Médical* of Dec. 2nd, M. Pierre Lereboullet has published an important paper confirming the great significance of epigastric pain as premonitory to diabetic coma. He relates two cases. A medical practitioner, aged 53 years, who had suffered from diabetes for a long time, was for some days so fatigued that he obtained a locum tenens, but there were no particular symptoms until the night of August 22nd, 1907, when he complained of severe pains in the epigastrium, slightly greater on the right side and radiating to the shoulder. The pains occurred in crises lasting some minutes, and were not accompanied by vomiting. In the morning M. Lereboullet saw him, and his first impression was that he was suffering from hepatic colic. But though the liver was slightly enlarged the region of the gall-bladder was not tender. The abdomen could scarcely be described as distended, and otherwise was negative. The intensity of the pains also suggested tabes, but there were no signs of this disease. But another symptom struck M. Lereboullet—Kussmaul's dyspnœa, with deep and difficult inspiration and sudden expiration, the patient nevertheless remaining in the dorsal decubitus position. The heart was normal and the pulse little accelerated. On bringing together the two symptoms, epigastric pain and dyspnœa, and the fact that the patient was a diabetic, M. Lereboullet feared the imminence of diabetic coma. Examination of the urine showed an abundance of sugar and Gerhardt's reaction. During the day, in spite of the administration of sodium bicarbonate in large doses, the pain persisted and the abdomen became tympanitic, and there was constipation. On the 24th the tympanites was increased, and the attacks of pain were still marked but less frequent. The pain was more diffuse. The temperature was subnormal and the patient became comatose. Death occurred some hours later, about 36 hours after the onset of the epigastric pain. In the second case M. Lereboullet saw in consultation a man, aged 60 years, in whom painful epigastric crises had suddenly appeared some hours previously. The abdomen was slightly distended and was tender only in the epigastrium. The temperature was normal and the pulse good. The patient had suffered from diabetes for a long time. The epigastralgia of the previous case caused M. Lereboullet to study the respiration which was dyspnœic, and he was inclined to think that the symptoms were premonitory of diabetic coma. Coma supervened and death occurred 11 hours after the onset. A long time ago Grube of Neuenahr described in diabetics a condition similar to the gastric crises of tabes with acetonuria and a chloroform-like smell in the breath, but terminating in recovery. His cases differed from those now described only in intensity. M. Lereboullet adopts the view that the pain is due to some auto-intoxication acting on the solar plexus. A similar pain has been described in uræmia and puerperal eclampsia. He points out the importance of recognising this pain as a premonitory sign of diabetic coma, for this enables the alkaline treatment to be adopted early. We may add that its recognition is important in another respect. In an annotation in THE LANCET of Nov. 27th, 1909, entitled "Abdominal Crises in Diabetes," we noticed a paper by two Melbourne observers, Mr. R. M. Downes and Dr. R. A.

O'Brien, in which an abdominal crisis occurred in two cases of diabetes, and suggested to several observers the necessity for abdominal operation. A well-nourished boy, aged 14 years, was admitted into the Melbourne Hospital in the early morning as a case of acute intestinal obstruction. At 6.30 A.M. on the previous day he vomited, and he seemed unwell during the rest of the day. Towards evening he complained of pain across the lower abdomen, and this increased up to the time of admission. For 36 hours neither fæces nor flatus had been passed, though he attempted to go to stool several times. During the day he vomited three or four times. About two hours before admission he became restless with a vacant expression. On admission he was only semi-conscious. He had suffered from diabetes for 18 months. The abdominal muscles were board-like. Mr. G. A. Syme was about to operate when the urine was found to contain much sugar and to give the ferric chloride reaction. The coma increased and death occurred on the following morning. At the necropsy the intestines were found normal. In the second case the glycosuria had disappeared at the time of the crisis, but the urine contained diacetic acid and a trace of acetone, which was attributed to intestinal obstruction. The moral is that the urine should be examined not only for sugar but for diacetic acid in all acute abdominal cases. It is noteworthy that while M. Lereboullet describes the abdominal pain as "épigastralgie," the Australian observers do not specially locate it in the epigastrium. Further, vomiting was present in both their cases, while the French writer noted its absence in his.

THE REHOUSING AT LIVERPOOL CRITICISED.

THE *Welldoer* is a monthly periodical which seeks to promote the organisation of charitable work in Liverpool, to awaken the public conscience in regard to the existing widespread distress, to criticise the management of local charities, and to deal with sociological questions generally If all this can be well done it will be very useful and good work, but the greatest care must be taken not to depreciate genuine endeavour. We have been favoured with an advance proof of an article that is about to appear on Liverpool rehousing, wherein it is suggested that about £1,000,000 have been spent on rehousing the Liverpool poor, and that the poor are not rehoused. We are told, "The slums have gone! Long live the slums!" This is a matter to which we have also given a good deal of attention, not only in London, in various parts of Europe, and in the United States, but likewise at Liverpool, and for the enterprise displayed in Liverpool we have expressed genuine admiration.[1] While congratulating the authorities at Liverpool for having placed their city in the forefront with regard to town planning and housing reform, we were never so sanguine as to imagine that they had abolished all their slums or that they had succeeded in satisfactorily rehousing all the poor people who were driven out of such slums as were abolished. But more care has been taken at Liverpool than is usually the case to admit only very poor people as tenants in the working-class dwellings built by the corporation. These tenements could easily be let at higher rents to a much better class of tenants, but to the great credit of the municipality of Liverpool they have considered the needs of public health and of the poor as of far greater importance than financial benefits. The article in the *Welldoer* admits that probably 50 per cent. of the dwellers of the ancient slums have been rehoused in the corporation buildings. If so, this is a higher proportion than obtains elsewhere; and to say further that these 50 per cent. are the *élite* of the dispossessed does not alter the fact. It shows that the problem is only half solved, and that this is perhaps the easier half; but something has been accomplished, be it only the easier half of so formidable a task.

THE DIAGNOSTIC VALUE OF ENLARGED LATERAL THORACIC GLANDS.

IN the *New York Medical Journal* of Dec. 9th, 1911, Dr. Morris Manges has discussed the diagnostic value of enlarged lateral thoracic glands, a point which has received little attention. In two cases of pulmonary growth he found small glands in the fourth and fifth intercostal spaces in the axillary line which on excision proved to be carcinomatous, and thus confirmed the diagnosis. This led him to investigate the subject. It may be remembered that the lateral thoracic lymphatics and glands follow the long thoracic vessels and convey the lymph from the lateral wall of the thorax, and that they communicate with the central group of axillary glands, which in turn empty into the supraclavicular glands. By anastomoses the lateral thoracic glands communicate with the subscapular, anterior thoracic, brachial, and mammary lymphatics. An exhaustive paper on enlargement of these glands has been published by von Zebrowski, who has found enlargement in 20 per cent. of all tuberculous patients and 2·5 per cent. of non-tuberculous.[1] In pulmonary or mediastinal conditions the lateral thoracic glands are seldom bigger than a pea or bean. This enlargement von Zebrowski explains in two ways. First, perforating lymphatics pass through the intercostal muscles and anastomose with the lymphatics of the costal pleura; when pleural adhesions exist there is also a communication with the pulmonary lymphatics. Another communication was worked out by Stephanis, who, by injections, discovered a retrograde path between the lateral thoracic glands and the posterior mediastinal glands through the medial intercostal lymphatics to the pleural lymphatics. Von Zebrowski states that there is a distinct relation between enlargement of the lateral thoracic glands and pulmonary tuberculosis. He found the enlargement usually on the side of the lung involved; it diminished with improvement of the pulmonary condition and sometimes disappeared with cure. Conversely the enlargement increased as the pulmonary condition became worse. He proved the presence of tuberculosis in the glands by microscopic examination. As tuberculosis is the commonest cause of the enlargement, its existence should cause the lungs to be repeatedly examined for early signs, which it may precede. Palpation of these glands should therefore be part of the routine examination of the chest. In this connexion the opinions of authorities with regard to axillary and cervical adenopathy is of interest. Sir William Osler states in his "Practice of Medicine": "Preceding the onset of pulmonary phthisis for months, or even for years, the lymph glands of the neck and axilla may be enlarged. These cases are by no means infrequent, and they are of importance because of the latency of the pulmonary lesions." The only writers besides von Lebrowski who specifically refer to enlargement of the lateral thoracic glands in tuberculosis are Hochsinger and De la Camp, who both regard this as positive evidence of bronchial or pulmonary tuberculosis in children, especially in infants, provided there is no inflammatory condition of the neighbouring skin. Dr. Manges has not found the glands so frequently enlarged as von Zebrowski claims. A routine examination has yielded only 25 cases in two years. In 4 cases pulmonary tuberculosis was present, and in all the enlargement was bilateral. Other conditions present were as follows: pulmonary and

[1] Deutsche Medizinische Wochenschrift, July 14th, 1910.

pleural neoplasms (5 cases; in all a gland was excised and examined; carcinoma was found in 2 and hyperplasia in the other 3); mediastinal neoplasm (1 case, microscopic examination showed only hyperplasia); carcinoma of breast (2 cases); carcinoma of liver (3 cases; all on right side; in 2 excised glands showed carcinoma); carcinoma of stomach (1 case with enlarged gland in fourth left intercostal space); carcinoma of skin (1 case); general carcinosis (1 case); lymphatic leukæmia (1 case); perihepatic abscess (1 case, an enlarged gland in the fifth space which disappeared after incision and drainage); Hanot's cirrhosis of liver (1 case). Dr. Manges concludes that while enlarged lateral thoracic glands are by no means frequent, they may at times give warning of pulmonary tuberculosis. They may also be of value in corroborating suspicions of malignant disease of the lung, pleura, posterior mediastinum, breast, or other distant organs. Enlargement does not necessarily denote either tuberculous or malignant disease, but may be due to hyperplasia: excision and microscopic examination are necessary to complete the proof.

OCCLUSION OF THE POSTERIOR INFERIOR CEREBELLAR ARTERY—A DEFINITE SYMPTOM-COMPLEX.

IN the *Albany Medical Annals* for October, 1911, is a valuable paper by Dr. Hermon C. Gordinier, of Troy, N.Y., on the occurrence of a very definite series of clinical symptoms from thrombosis or occlusion generally of the posterior inferior cerebellar artery. These are so characteristic that it is curious so few instances of the condition have been put on record. Five cases have been reported in America, exclusive of three published in the present paper, one in England,[1] two in France, and 16 in Germany. It may be recalled that the posterior inferior cerebellar arteries are the longest branches of the vertebral arteries. They arise from the latter about 2 centimetres below the formation of the basilar artery, and pass outwards and backwards, winding round the side of the medulla oblongata between the hypoglossal and pneumogastric nerve roots; they then leave the side of the medulla along the inferior cerebellar peduncle and so reach the vallecula of the cerebellum, on the under surface of which they anastomose with the middle and superior cerebellar arteries. Occlusion of the posterior inferior cerebellar artery, owing to this free anastomosis, concerns mainly, if not solely, the small terminal branches which that vessel gives to the medulla as it winds round it. These small terminal vessels supply a sharply limited area on the lateral aspect of the medulla, which includes the formatio reticularis and restiform body, and is bounded by the olive anteriorly. Its vertical extent is, roughly speaking, from the middle of the hypoglossal nucleus to about the level where the restiform body passes into the cerebellum. The main structures implicated in this area are the spino-cerebellar tracts of Gowers and Flechsig; the descending roots of the fifth cranial nerve and perhaps also of the eighth; olivo-cerebellar fibres; the intramedullary parts of the ninth and tenth cranial nerves; and certain important vasomotor and sympathetic fibres running in the formatio reticularis. Occasionally the auditory nuclei and nerves may be involved, but not the pyramidal tract, the seventh or sixth cranial nerves, nor the fillet, unless the thrombus extends into the vertebral artery. All these structures are implicated by a lesion the cross-section of which is less than that of a threepenny-piece. The clinical symptoms, in a pure case, are as follows: sudden onset without loss or disturbance of consciousness; crossed analgesia and loss of temperature sense—face on same side as lesion, body, arm, and leg on side opposite to lesion (face from implication of the descending root of the fifth, opposite side of body from implication of spino-thalamic sensory fibres in the formatio reticularis); no impairment of touch, or of localisation (the median fillet intact); ataxia in limbs on same side as lesion (involvement of spino-cerebellar tracts and olivo-cerebellar fibres); tendency to fall to the side of the lesion (restiform body); vertigo, sense of rotation, giddiness, vomiting (vestibular and vagus nerves); paralysis of the palate, vocal cord, and muscles of deglutition on the same side as the lesion, with impaired sensation of pharynx (ninth and tenth cranial nerves); involvement of cervical sympathetic on same side as lesion—enophthalmos, unilateral sweating, ptosis, small pupil—(central sympathetic tracts in formatio reticularis). Dr. Gordinier describes three excellent cases of this remarkable affection, which presents a clear and definite syndrome, easily recognisable clinically and pathologically. The multiplicity of the symptoms in association with the small region affected constitutes the striking feature of the syndrome. Any case which shows a crossed anæsthesia (pain and temperature) and unilateral paralysis of palate and vocal cord should always suggest a lesion in the distribution of the posterior inferior cerebellar artery in its medullary part, and when the other symptoms enumerated above—e.g., unilateral ataxia and unilateral involvement of the cervical sympathetic, are present, the exact site of the disease can be delimited with conspicuous ease and certainty.

THE MINISTRATIONS OF THE EARTHWORM.

AMONGST other interesting articles published in the January number of *Science Progress* is one by J. Newton Friend, Ph.D., D.Sc., on the aeration of the soil by earthworms. As the writer points out, the chief activity of worms lies in their power of excreting acids in their castings, of exhaling carbon dioxide, and of aerating the soil both by mechanical and by chemical means. He has made a number of observations on these points which show that the rôle of the earthworm amply repays study. Worms effect the aeration of the soil in a variety of ways. In burrowing through the soil the worms render it more porous and permeable to gases, not merely by virtue of the air spaces formed, but by reason of the fact that the soil is thus continually kept in gentle motion. Again, the soil passing through the bodies of worms is excreted in a finer condition, being ground by attrition through the intestines. This increased fineness up to a certain limit means increased area, and hence greater susceptibility to the action of gases; beyond this limit the particles begin to cling together, and a proportionately less porous mass results more resembling clay than ordinary soil. It was Darwin who estimated that no fewer than 15 tons of soil annually pass through the bodies of worms for every acre. Further, worms breathe in oxygen and exhale carbon dioxide, and the latter gas, as is well known, readily dissolves in water, forming an acid solution which will render alkaline earths and metallic oxides—e.g., iron—soluble. The amount of carbonic acid gas exhaled in the course of a year by an active worm-inhabited acre would amount to 29·6 kilogrammes, or 15,000 litres. The interchange of oxygen and carbonic acid gas effected by worms is thus considerable. Worms materially aid in producing soluble salts of iron in the soil when other agencies (e.g., dilute mineral acids) fail. The iron is eventually given back to the soil in a more soluble condition, and presumably in one which can be directly absorbed by plant roots. As Dr. Friend points out,

worms probably have an important ministry to perform in the soil, and it is to be hoped that further researches in this direction will be undertaken, for the habits and distribution of the earthworm appear to have received little attention since the days of Darwin, or with the aid of modern scientific apparatus.

THE SPIROCHÆTA GALLINARUM.

THE study of the life-history of the malarial parasite was greatly assisted in its early stages by investigations made on allied organisms occurring in the bird. The research on the life-history of the spirochæta gallinarum conducted by Mr. E. Hindle, one of the Beit Fellows, is similarly of value, since the comparative study of this organism may serve to fill lacunæ in our knowledge of the allied spirillum of African tick-fever. Mr. Hindle has brought forward evidence making it almost certain that longitudinal division of the organism does not occur, and explains the deceptive appearances which have led to that belief. The work of previous observers on the formation of coccoid bodies at the crisis of the disease and as the result of drug treatment was confirmed, and Mr. Hindle agrees with Leishman that transmission of the disease is not caused by the direct bite, but by the infection of the bite with the coccoid bodies contained in the coxal fluid and excrement. The coccoid bodies mentioned above do not usually develop in the fowl, but similar bodies derived from spirochætæ which have been ingested by, and have bored their way into, the cells of the various organs of the tick will, when they gain access to the blood of the fowl, develop into the ordinary spirochæta form. This last step has, however, not been followed. Experiments suggested that possibly it is the coxal fluid which enables the coccoid bodies derived from the tick to develop into spirilla in the fowl. The development of the coccoid bodies into spirochætæ and fusiform bacilli has been followed in the tick and in the eggs laid by the infected ticks, and it was shown that larvæ hatched from these eggs could infect the fowl when fed upon them. Experiments appeared to show that in order that the coccoid bodies may develop into spirochætæ they must escape from the cells into a fluid medium, which in the tick is either the cœlomic fluid or the contents of the gut.

MESO-THORIUM IN MEDICINE.

AT the conclusion of his lecture before the members of the Royal Institution on Feb. 2nd on the Vital Effects of Radium and Other Rays, Sir James Mackenzie Davidson dwelt upon the possibility of other radio-active substances than radium proving of value in treatment. Uranium, thorium, and actinium, he said, had all been suggested in this connexion, but they were too feebly radio-active to possess any real efficacy. The discovery by Otto Hahn of the substance known as meso-thorium, however, had aroused considerable expectation. Meso-thorium, which was one of the disintegration products of thorium, and was found in the course of an attempt to separate radio-thorium directly from thorium, emitted the same rays as radium, and weight for weight was more powerful. As the supply of thorium was much larger than that of pitchblende, from which radium was obtained, they might hope to have a larger supply of meso-thorium than of radium at the general disposal. It would cost much less, but, on the other hand, it had a short life of only about seven years. The lecturer produced a tube of meso-thorium, which, he said, was equivalent to 10 milligrammes of pure radium. He had applied this to a chronic patch of X ray dermatitis on his hand, and a reaction followed 15 days after application. This latent period was rather longer than in the case of a similar application of radium, which he had used successfully in the treatment of his X ray burns, but the result with the meso-thorium promised to be equally favourable. As to radium-therapy, the lecturer said that in the condition of the eyelids known as "spring catarrh" and in X ray dermatitis he had proved it to have a value which no other method of treatment apparently possessed. Radium also had a destructive influence upon large rapidly-growing tumours like sarcoma, which could be subverted by the method of burying tubes within them, thus furnishing another illustration of the fact that radium, like other rays, concentrated its attack upon the young and most rapidly-growing cells. That was probably the reason why sarcomas were so vulnerable to attack when compared with carcinomas, which were of slower growth. But in spite of its greater potency and convenience in application, the same thing had to be said of radium as he had already said of the X rays, that it could not in any sense be looked upon as a cure for cancerous growths of large size. It would inhibit the growth of such tumours and destroy them locally, but rarely completely, and it did nothing to prevent the usual secondary deposits. With regard to the emanation of radium, he produced a standard which Sir William Ramsay had given him, containing in a little bottle 1/40,000th of a milligramme of pure radium. Sir William Ramsay's standard is apparently intended to replace the Maché unit.

TRACHOMA BODIES.

ANY investigation, even of a negative character, which serves to throw light on the cause of the infectious character of so troublesome a disease as trachoma is to be welcomed. The bacteriology of trachoma is at present a series of negations, and this is especially unfortunate, as the disease has such ill-defined clinical boundaries that the discovery of the specific cause would alone render possible any real advance in its study. Secondary infections are so frequent in this disease that not unnaturally numerous organisms have been credited with its causation, whose claims in this respect have subsequently been shown to rest on no substantial basis. One of these, the trachoma body described by Halberstaedter and Prowazek, has claims which are difficult to disprove. These bodies were regarded by their discoverers as being true parasites belonging to a new group of intracellular organisms—the chlamydozoa. Their non-specific character has, however, been shown by finding them in cases other than trachoma, and even in very slightly inflamed or normal conjunctivæ. A recent paper by Dr. S. B. Wolbach and Dr. S. Hanford McKee carries the matter further by furnishing a probable explanation of the true nature of these trachoma bodies, which, as the authors show, occur only in those portions of the conjunctival epithelium which are the most injured, and where typical mucus-secreting cells are absent. A careful study of the bodies by smear preparations and in sections, together with comparative studies of other mucus-secreting surfaces, have led these investigators to the conclusion that the trachoma bodies represent mucous secretion under pathological conditions, and consequently that their parasitic nature is disproved.

UTERINE CANCER AND ITS EARLY DIAGNOSIS: ORIGINAL RESEARCH FROM SUBJECTIVE SYMPTOMS.

Dr. E. Atlee, in a recent paper on the Early Diagnosis of Uterine Cancer, points out that all clinicians realise the importance of obtaining the earliest possible knowledge from subjective symptoms of cancer formation. He maintains that the victims of uterine cancer are frequently women of excessive weight, but the scientific physician has not as yet taken into consideration the possibility that the feature of weight may be a help in connexion with an early diagnosis of the disease. The point of importance, according to the author of this paper, is not the actual weight of

the individual, but the comparative weight of that individual at different periods. In the furtherance of this view 24 cases have been carefully studied, and the testimony points almost conclusively one way—viz., that the incipient stage of cancer of the uterus is coincident with the maximum weight of the woman irrespective of age, and that the duration of this incipient stage may vary as does that of the recognised stage of the disease. It is not maintained that the existence of the maximum weight is alone sufficient to determine the presence of uterine cancer, but associated with the history of maximum weight will be found one of unexcelled health and strength. A further point insisted on is that this maximum weight, health, and strength have been attained rapidly subsequent to previous imperfect health conditions. A chart is given of what Dr. Atlee believes to be the probable characteristic phenomenon in the progress of cancer cases covering a period of 12 years or more. In this chart a period of poor or indifferent health is represented as followed by a period of rapid return to perfect health and strength, with maximum weight, and then the occurrence of suspected and recognised cancer. Curves are also given for uterine diseases other than cancer, and for cancerous diseases in women other than in the uterus, and in both these conditions the curve is represented as being one mainly of a continued period of impaired health. Lastly, a table is given to show that the maximum weight of healthy women generally occurs at an age other than that at which the greatest incidence of cancer of the uterus occurs. Dr. Atlee is appealing to physicians to fill up tables of questions in order to extend his researches so as to obtain a larger series of cases. The idea is a novel one, and, of course, a very much larger amount of material is necessary than the 24 cases on which the author appears to rest his hypothesis. And we are not told how the curves have been constructed; they appear merely to represent the author's impressions. It seems to us unlikely that further investigations will corroborate the suggestion put forward by Dr. Atlee.

THE VISITATION OF THE SICK.[1]

IN mediæval times the sick man, with the sense of humour which characterised mediæval religion, added some private devotions of his own to the official services for the sick prescribed by the Church. That is to say, before he took his medicines he was accustomed to repeat Psalms LV. and LVIII. in the Vulgate, which correspond to LVI. and LIX. in our Book of Common Prayer. In the former of these psalms the patient declares that he will not fear what flesh can do unto him, and in the second he prays to be delivered from the bloodthirsty men, "de viris sanguinum salva me." Whether these aspirations were used by the patient in regard to his parish priest or his doctor, or merely symbolically in reference to the powers of evil who were then credited with bringing sickness, cannot now be definitely stated, but it seems that the mediæval patient had qualms as to both his spiritual and his bodily advisers. Sickness is ever with us, and there is as much need now, as in former days, for wise coöperation between the physicians both of the soul and of the body. The little book now before us contains much sound practical common sense within the 50 pages which are allotted to instruction by the medical man and the cleric respectively. Each little treatise may well be studied by the members of the other profession, and we are glad to see that both authors recognise a fact that is sometimes in danger of being forgotten by both medical men and the clergy—namely, that a patient, whether he be sick in soul or body, or both, is first and foremost a man and not merely "a case." Sir Dyce Duckworth in his preface expresses an "entire concurrence with the opinions set forth," with which we are in general agreement.

[1] Practical Hints for Pastoral Work among the Sick. By H. Gordon Mackenzie, M.A. Oxon., M.B. Durh., and Notes and Suggestions on Visiting the Sick, together with Short Service and Private Devotions for the Sick, compiled by the Rev. Archibald O. Hayes, M.A., Hospitaller of St. Thomas's Hospital. With an Introduction by Sir Dyce Duckworth, Bart., M.D. Edin. LL.D. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1911. Pp. 80.

OUTBREAK OF TYPHOID FEVER DUE TO A BACILLUS CARRIER OF 46 YEARS' STANDING.

IN the *Journal of the American Medical Association* of Jan. 6th Dr. C. Bolduan, acting assistant to the general medical officer, and Mr. W. C. Noble, bacteriologist, department of health, city of New York, have reported an outbreak of typhoid fever due to a bacillus carrier under remarkable conditions. Towards the end of August, 1909, a sudden increase in the number of cases of typhoid fever reported from the boroughs of Manhattan and Bronx attracted attention. A certain milk-supply was common to all and was cut off on Sept. 1st. However, additional cases were reported in diminished number all through September, making a total of several hundred. The cases reported in September were ascribed to secondary infection in the city. On tracing the milk-supply back to its origin, it was found to come from the village of Camden. The former manager of the creamery there was suffering from typhoid fever, but judging from the date of onset was one of the victims of the infection and not its cause. Further inquiry showed that there had been undue prevalence of typhoid fever at Camden for years. On one dairy-farm there had recently been a case of typhoid fever. The dairyman was born in Wisconsin in 1848 and had typhoid fever there in 1863 or 1864. He went to Camden in 1866 and began to sell milk in 1873. In 1878 his two-year-old daughter had enteric fever, and during her convalescence her grandmother, who had nursed her, became very ill and was delirious for three weeks. The disease was called "gastric fever." In 1886 a man working on the farm was very ill with fever for several weeks, which was diagnosed "gastric fever." In 1893 another daughter was ill in the autumn and typhoid fever was diagnosed. In 1897 still another daughter had what was called "intermittent fever." In 1893 another worker on the farm had typhoid fever. In 1909 still another worker died from the disease. Such a history suggested a bacillus carrier, and specimens of fæces were obtained from the whole household. Those of the dairyman gave an almost pure culture of typhoid bacilli on Conradi-Drigalski plates. Subsequent examinations made after a month and a year gave similar results. This dairyman was a better-class farmer who kept his home and his dairy much cleaner than the average dairyman. Moreover, he was personally clean. The case is important, as it shows that milk may be infected by a typhoid carrier, though he be cleanly in his habits.

THE first of the three Lettsomian lectures on Glycosuria was delivered by Dr. A. E. Garrod before the Medical Society of London on Feb. 5th. The second and third lectures will be delivered on Feb. 19th and March 4th respectively. The anniversary dinner of the society will be held on March 6th, at 7.30 P.M., at the Whitehall Rooms, Hôtel Metropole.

THE Harben lectures of the Royal Institute of Public Health will be delivered in the lecture-room of the institute on Feb. 26th, 27th, and 29th, at 6 P.M., by Professor Simon Flexner (director of the Rockefeller Institute for Medical Research, New York), the subject being "The Local Specific Treatment of Infections."

AN EXAMINATION OF THE MEDICAL PROVISIONS OF THE NATIONAL INSURANCE ACT.

BY WILLIAM A. BREND, M.A. CAMB., M.B., B.SC. LOND.,

OF THE INNER TEMPLE, BARRISTER-AT-LAW; LECTURER ON FORENSIC MEDICINE, CHARING CROSS HOSPITAL.

I.

UNDER any circumstances the National Insurance Act is bound to have a far-reaching effect upon the future of medicine in the British Isles. If it comes into operation in its present form, it will affect at once and directly more than 13,000,000 people. If for any reason some of its provisions should be found unworkable, sooner or later they will be succeeded by other efforts of the Legislature to bring about the result desired. For the Act must not be looked upon as an isolated step, but as the culmination of a movement for the provision of better medical attendance and treatment among the working-classes which has been growing for years. In its general principles it has received the assent of both the great political parties of the State, and the responsibility therefore of carrying it, or an analogous measure, to a successful issue becomes a national one. It behoves the medical profession accordingly not to commit itself to a line of action definitely hostile to the Act until its provisions and their probable effects have received the minutest consideration. Further, the possibility of the introduction of alternative schemes must constantly be kept in mind. It might be better to "bear those ills we have, than fly to others that we know not of."

It is not necessary here to emphasise the deplorable lack of adequate medical attendance and treatment among the working classes. Its evils have been pointed out by public and private inquiries, and recently both the Majority and Minority Reports of the Royal Commission on the Poor-law stated that ill-health was a fruitful source of destitution. The conditions under which medical attendance is given are frequently demoralising both to patient and doctor. The medical profession would be the first to admit that something must be done, and the Insurance Act is at once a recognition by the State of its responsibility and an attempt to discharge its obligations. It would be waste of time now to discuss alternative schemes, but one which has been mentioned, though not by any responsible person, deserves passing consideration. It has been suggested that medical officers should be appointed at fixed salaries to attend insured persons in each district, and it is calculated that nearly 7000 could be so appointed at salaries of £600 a year each, for the amount it is now proposed to spend on medical benefit. If such a scheme were seriously brought forward united medical action would be more difficult to secure than at present, and hostility to it might be ascribed by public opinion to regard for vested interests.

One other general effect must be mentioned. The Act establishes a closer relationship between the State and the medical profession than has ever existed before. If the State is going to draw so largely upon the services of the medical profession it becomes more than ever its duty to take note of its recommendations and to safeguard it in the discharge of its services. Public opinion will demand that this be done. In the past the profession has had just cause to complain of the treatment it has received at the hands of the Legislature. Important matters, as, for example, the reform of the laws relating to coroners and inquests, or to the certification of death, have been postponed indefinitely. Measures such as the Midwives Act and the Notification of Births Act have imposed fresh duties upon medical men for wholly inadequate remuneration or even none at all. An Act to prevent the abuse of medical titles, and restrict the operations of herbalists, patent medicine vendors, and quacks of all sorts is long overdue. In its new position the medical profession will have an increased right to demand the remedying of these grievances, and the organisation which the Insurance Act has led to will give it added power to enforce this right.

In the opinion of the writer it is open to question whether the Insurance Act has yet received adequate and unbiassed consideration from many medical men. Our political system almost necessarily entails that a person approaches such a measure prejudiced either for or against it according to the party to which he belongs. Condemnation of the Act as "socialistic," even if justified, merely tends to obscure the purely medical points at issue and lends colour to the assertion that political bias is being displayed. The time which elapsed between the introduction of the Bill and its passage into law did not permit of full determination being made of the effects of the scheme, for many of these depended upon the collection and collation of statistics. Finally, few doctors can have had leisure to study in detail for themselves a complex Act of 83 Sections and 5 Schedules, which underwent frequent drastic changes during its progress.

Some Errors.

A word of caution is required as to the necessity for meticulous accuracy in statements made to illustrate the grievances of the medical profession. Success in any campaign depends largely upon the support of public opinion, and this will not be won if assertions are made which can be easily refuted or are based upon unjustifiable assumptions. This has sometimes been the case, and the following are cited as instances of the errors medical men are liable to make under the influence of haste or indignation.

In the *Times* of Jan. 16th a medical man quoted and amplified figures which tended to show that, on the average, each doctor who works under the Act will receive in respect of insured persons "the magnificent gross sum" of £253 per annum, "from which one-third to two-thirds, according to locality, will have to be deducted for horses, grooms, motors, chauffeurs, rent of consulting-rooms, rates, and in most cases cost of drugs and dispensing—and this for men whose professional education has cost from £1000 to £2000 ..... and whose goodwills have cost on an average £1000 to £2000." He wrote as though £253 were to be the total average medical income of the future, whereas it will be derived from less than one-third of the community, and that roughly the poorest third. The figures are probably not correct, but from his argument it follows that were the whole population of Great Britain, instead only of 13,000,000, insured at the same rate, the average medical income would be nearly £800 per annum, a position not so distressing as to excite much lay sympathy.

A frequent fallacy is to compare insured persons with patients. Instances of this occur in the leading article of the *Times* of Dec. 29th, 1911, and in a letter from a medical man in the same journal of Jan. 17th. In the latter case the writer states that 41 per cent. of his private patients will become contract patients under the Act. He finds that now he sees each of these on the average five times in the year, and receives 10*s.* 6*d.* per individual. Deducting 1*s.* 6*d.* for medicines he will in the future, he says, receive 4*s.* 6*d.* from each of instead of 9*s.* He concludes, therefore, that he will lose one-fifth of his income. The writer forgets that the names on his books are only those of patients—i.e., persons who have actually received medical attendance within the period under review. Under the Act he will be paid in respect of a larger number of insured persons some of whom will not consult him at all, and others much less than five times. He has probably no means of computing what this number will be. As regards attendances, if the average number per patient is five, the average number per insured person is likely to be appreciably less.

In the *British Medical Journal* of Jan. 13th is an editorial paragraph headed "Payment under the Insurance Act," in which certain figures are quoted from statements published by medical men in support of the demand for a higher rate of remuneration. The first of these is a long detailed statement from two medical practitioners which appeared in the *British Medical Journal* of May 27th, 1911. Careful study of this document shows that the conclusions finally drawn anticipating substantial loss under the Act are based upon certain untenable assumptions. Further, the figures given for actual attendances upon all classes during four weeks do not support these conclusions. But in any case the statement is of little value, since it was compiled before the Act was amended. Allowance would now have to be made for the effect of such changes as the imposition of an income-limit for voluntary contributions, &c. The second quotation is from a letter which appeared in the *British Medical Journal* of Dec. 2nd, 1911, wherein a doctor anticipates that he will be required to attend each insured person 6½ times, at an average fee of about 7*d.* an

attendance. These figures, however, are based upon those of a provident dispensary in which all the lives are unselected, and the bulk of the members women and children, and therefore not comparable to the insured population. The paragraph concludes with a statement that "a medical practitioner whose patients mainly consist of insured persons will have to work uninterruptedly for at least 10 hours a day if he wishes to make a net income of even as little as £250 a year." Now this sum will be earned (at 4*s*. 6*d*. a head) if he has 1100 insured persons on his books. If each of these is seen five times during the year, and it will be shown later that the average number of attendances is likely to be less than this, it would be necessary to give on the average 15 attendances a day. It cannot be seriously contended that this would entail 10 hours' uninterrupted work, especially as no time would be spent in dispensing.

Statements such as the above place weapons in the hands of adversaries.

Points to be Considered.

The points about the Insurance Act especially requiring consideration by medical men are the economic position of the beneficiaries, the income limit, the degree of control over administration the medical profession will possess, the work to be done, the remuneration, and the effect upon the progress of medical science. Some of these are covered by the Act itself, others depend largely upon the regulations to be issued by the Commissioners.

The Beneficiaries.

Who will come under the scheme? This is a most vexed question and goes to the root of the medical grievances. The most detailed statement as to the persons anticipated to become insured is to be found in the actuaries' report, and in the appendix to the report are given the numbers engaged in each kind of occupation. It is a valuable and interesting document, but of course some of the conclusions are based upon estimates or assumptions which may in practice prove to be quite ill-founded. They are quoted provisionally in the absence of more reliable figures.

Compulsory contributors.—With certain scheduled exceptions the Act requires all employed manual workers, and all persons otherwise employed whose income from all sources is below £160, to become insured. The most important exceptions are persons employed under the Crown or public authorities, clerks and other salaried officials in railway and other companies, who are already insured for benefits not less favourable than those given by the Act, and school teachers who come under Superannuation Acts. A glance at the actuaries' reports shows that the great bulk of persons in this class will be working men and women. The principal occupations with the numbers engaged therein, according to the Census of 1901, excluding Ireland, are:—

	Employed.	Working on own account.
Domestic offices or services	2,196,147	..... —
Conveyance by rail, road, sea, docks, &c.	1,385,413	 29,460
Agriculture	1,299,347	 29,172
Textiles	1,282,765	 36,043
Building	1,060,421	 52,496
Mines and quarries	913,101	 13,215
Dress	902,411	 290,131

There are nearly half-a-million general labourers, but the above figures will certainly include practically all good-class artisans, many of whom are accustomed to paying remunerative medical bills. There are also nearly 400,000 persons in positions generally looked upon as better than that of the working man, the most numerous being business and law clerks, commercial travellers, and sick-nurses. Compulsory contributors will endeavour in the first instance to become members of approved societies, and these societies have full power to make their own rules for admission of members, with the one proviso that they may not refuse a person solely on the ground of age. Compulsory contributors who are refused admission become

Deposit contributors.—It is important here to quote the Act. They are defined as "insured persons ..... who have not joined an approved society within the prescribed time, or who, having been members of an approved society, have been expelled or have resigned therefrom and have not within the prescribed time joined another approved society." It is commonly assumed that members of approved societies will be all picked lives, and deposit contributors bad lives. While this will, no doubt, be in the main true, it will be noticed that it is not the statutory distinction. The Act says nothing about good or bad lives. An approved society may if it chooses admit members without any medical examination at all; it may be quite worth while for some of them to do so. Equally, a person compulsorily insured may fail to become a member of an approved society for reasons other than ill-health. Bad lives may therefore be found among members of approved societies, and good lives among deposit contributors. This is of importance in view of the statement made by the Chancellor of the Exchequer at the Special Representative meeting of the British Medical Association on June 1st, 1911. According to the *British Medical Journal Supplement*, of June 3rd, he said: "There is only one thing I would say about the Post Office contributor, and that is that the 6*s*. basis does not come in in that case. You certainly cannot be expected to take people who are already ill at that rate. The reason we thought the 6*s*. was fair was that you will be getting it for people who were well as well as those who were ill. When you come to the Post Office contributors they would be people who are already ill, and we certainly never contemplated that the 6*s*. should be for those." Now while it is true that this was said *à propos* of deposit contributors, the spirit of the promise clearly is that bad lives shall be treated at a higher rate. As quality of life is not the criterion distinguishing between deposit and other contributors, presumably effect will be given to the promise by means of the regulations which the Commissioners are to issue. If this interpretation is correct, the medical profession will have the advantage of a voice in the framing and carrying out of these regulations which it would not have had if the distinction had depended upon the rules of approved societies. To be able to insist upon a medical examination for all insured persons, irrespective of class, before admission to medical benefit at ordinary rates would be a right of considerable value.

Voluntary contributors.—These are persons not employed within the meaning of the Act, who either (*a*) are engaged in some regular occupation and are wholly or mainly dependent for their livelihood upon the earnings derived by them from that occupation, provided that their total income from all sources does not exceed £160 per annum, or (*b*) have been insured persons for a period of five years or upwards. In the latter case the income-limit does not apply. Under this section it will eventually be possible for persons to derive benefits from the Act who, though starting poor, have become wealthy since they first began to contribute.

The actuaries estimate that the number of persons who will become voluntary contributors, excluding Ireland, is about 616,000, or less than 5 per cent. of the total. Medical men fear that many of their best paying lower middle-class patients will take advantage of these provisions. It is very difficult to determine who will come in, but in making an estimate certain checks in addition to those enumerated above must be borne in mind. In the first place, voluntary contributors have not only to pay their own contributions but also the amount which would have been paid by their employers had they been employed within the meaning of the Act. Secondly, contributors over the age of 45 (and others who fail to join within the first six months) have to pay a higher contribution in accordance with tables to be prepared by the Insurance Commissioners. Thirdly, persons wishing to become voluntary contributors who are refused by approved societies cannot become deposit contributors.[1] They drop out of the scheme altogether. As probably the most frequent ground of such refusal will be ill-health, it means that the worst lives among such persons, and those therefore most remunerative from the medical point of view, must still remain private patients.

The terms of admission to insurance at least are rigidly defined in the Act, and whatever the inducements it may hold out to persons to obtain medical treatment at contract rates, though they can well afford to pay doctors' bills, it is none the less possible that it may check this same abuse in other directions. For the grievance is no new one. It has been a sore point with the profession for a long time that persons in good social position obtain medical attendance through friendly societies. Now some of such persons

[1] This view has been challenged, but I cannot otherwise interpret Sections 1 and 42 of the Act.

at least will be ineligible for insurance in the future, and must perforce attend a doctor privately.

The Income-Limit.

The foregoing considerations apply to eligibility for insurance, but it does not necessarily follow that all insured persons will receive medical treatment at a fixed capitation or other fee. Section 15 (3) provides that—

> The regulations made by the Insurance Commissioners shall authorise the Insurance Committee by which medical benefit is administered to require any persons whose income exceeds a limit to be fixed by the Committee, and to allow any other persons, in lieu of receiving medical benefit under such arrangements as aforesaid, to make their own arrangements for receiving medical attendance and treatment (including medicines and appliances), and in such case the Committee shall, subject to the regulations, contribute from the funds out of which medical benefit is payable towards the cost of medicine, attendance, and treatment (including medicines and appliances) for such persons sums not exceeding in the aggregate the amounts which the Committee would otherwise have expended in providing medical benefit for them.

It is said that this provision is of little value for the reason that it can only be put into force by the Insurance Committees, and that on these the medical profession will have small representation. This aspect of the matter will be considered under the heading of "control of medical benefit." Assuming for the moment that it will be effective, it is obviously a valuable means of checking abuse. For not only will the persons excluded be required to make their own own arrangements, but they will be in a better position to do so inasmuch as they will still receive medical benefit in the form of a sum of money.

The point which in the opinion of the writer is open to question is the advisability of the profession insisting upon a specified income-limit being applied to the whole country by an amending Act; or of local groups of medical men declining to have anything to do with the Act until the Insurance Committees have fixed income-limits. In the first place the profession is not united as to what the amount of income should be. £104 a year has been agreed upon as a compromise, but many doctors think this too high. Further, a man's income is not a satisfactory test of his ability to pay for medical attendance. A single man with 30*s.* a week may be much better off than one with £2 a week who has a wife and family to support. Again, owing to variations in the rates of wages and prices of necessities an income-limit which would be equitable in one district would not necessarily be so in another. By leaving the matter to be determined independently in each locality allowance can be made for varying conditions. Nor is there anything in the Act to prevent two or more income-limits prevailing in one district, income-limits, for example, varying on an ascending scale with the number of a man's dependents. In some localities, too, the medical men might be willing to waive the income-limit or consent to a higher income-limit, in return for an increased capitation fee all round or some other concession. Such details could not be dealt with in an Act of Parliament. In this and other matters much will depend upon the regulations which the Commissioners will issue. Under these circumstances is not the *non-possumus* attitude a little premature? There is no need to come to a decision at once.

The next step presumably is the appointment of the Advisory Committee. Promise has been given that the profession shall have a voice in the appointment of the medical members of the Committee, who must be general practitioners of experience. The profession will thus be able to assist in framing the regulations, without in any way committing itself to working under the Act.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Feb. 1st, Mr. RICKMAN J. GODLEE, the President, being in the chair.

The SECRETARY reported the death, on Jan. 24th, of Sir Henry Trentham Butlin, Bart., member of the Council and Past-President.

The following vote of condolence was passed:—

> The Council hereby record their deep regret at the death of their colleague, Sir Henry Trentham Butlin, Bart., for whom they entertained the warmest feelings of personal friendship, and they desire to express their very sincere sympathy with Lady Butlin and the other members of the family in their bereavement. The Council do also record their appreciation of the distinction and ability with which Sir Henry Butlin fulfilled the duties of President of the College and member of the Council and their grateful sense of the many services rendered by him to the College and the medical profession. The Council believe that no member of the profession more fully enjoyed the confidence and esteem of his colleagues, and his devotion to duty in failing health and increasing infirmity will be treasured by them as a priceless example of courage and unselfishness. For these reasons, as well as for his admirable skill in practice, they are assured that his name will always be held in honour and kindly remembrance.

It was resolved that Diplomas of Membership should be granted to 91 successful candidates, and that in conjunction with the Royal College of Physicians of London Diplomas in Public Health should be granted to 18 successful candidates.

Mr. J. Ernest Lane was re-elected a member of the Court of Examiners.

A letter was read from the Assistant Secretary of the Joint Committee for National Health Insurance, stating that the National Health Insurance Joint Committee and the Insurance Commissions for England, Scotland, and Wales respectively proposed to hold a conference on Feb. 2nd with representatives of the medical profession and inviting the College to appoint two members to attend the conference. It was resolved that the following reply should be sent to the National Health Insurance Commissioners:—

> The Council regret that they are not prepared to send representatives to the meeting suggested by the National Health Insurance Commissioners. The Council are of opinion that the administration of the medical benefits cannot be carried out under the Act with due regard to the interests of the public and the welfare of the medical profession, and that no satisfactory arrangement can be arrived at without an amending Act. The Council, however, will be prepared to render any assistance in their power in the drafting of an amending Act for the provision of such amendments as are necessary to secure the coöperation of the medical profession.

The Standing Committee of the Council on the National Insurance Act were instructed to take steps to communicate with other medical corporations with a view to united action with regard to the Insurance Act.

A report was presented from the Dental Education Committee, containing a statement upon dental education in London which had been prepared in response to a request from the Royal Commission on University Education in London. This was approved, and the President and Sir Alfred Pearce Gould were nominated as witnesses to represent the College before the Commission and to give any further information on the subject that might be required.

Mr. C. H. Golding-Bird was re-elected as the representative of the College on the Central Midwives Board for the year from March 31st next.

The PRESIDENT reported that he had chosen Mr. C. W. Mansell Moullin as Bradshaw lecturer for the ensuing collegiate year.

The SECRETARY pointed out that in the report of the General Medical Council on the final examinations of the dental licensing bodies the proportion of marks which candidates at the examinations for the licence of the College must obtain in order to pass was given as two-fifths, whereas three-fifths is the proportion required, and that steps had been taken to correct the error.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8300 births and 6278 deaths were registered during the week ending Feb. 3rd. The annual rate of mortality in these towns, which had been 15·4, 14·8, and 16·5 per 1000 in the three preceding weeks, further rose to 18·6 per 1000 in the week under review. During the first five weeks of the current quarter the mean annual death-rate in these large towns averaged 16·1 per 1000, while in London during the same period the average annual death-rate did not exceed 15·5 per 1000. The annual death-rates in the several towns last week ranged from 6·9 in Ilford, 9·0 in Enfield, 9·7 in Bath, 10·1 in Great Yarmouth, and 10·4 in Ealing, to 27·4 in Dudley, 28·1 in Barnsley, 30·9 in Bury, 31·0 in Preston, and 31·4 in Walsall.

The 6278 deaths from all causes in the 94 towns were 719 in excess of the number in the previous week, and included 401 which were referred to the principal epidemic diseases, against 297 and 311 in the two preceding weeks. These 401

deaths from the principal epidemic diseases included 166 from whooping-cough, 71 from diphtheria, 67 from infantile diarrhœal diseases, 63 from measles, 21 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 1·2 per 1000, or 0·3 above the average in the four preceding weeks. The deaths attributed to whooping-cough, which had been 88, 81, and 94 in the three preceding weeks, further rose to 166 last week, and caused the highest annual death-rates of 1·6 in Leicester and in Barrow-in-Furness, 1·7 in Rhondda, 1·8 in Swansea, 2·6 in Bury, 2·9 in Gillingham, 3·0 in Barnsley, 3·8 in Merthyr Tydfil, and 7·3 in Walsall. The deaths referred to diphtheria, which had declined from 69 to 53 in the three preceding weeks, rose to 71 last week, and included 19 in London and its 14 suburban districts, 5 in Liverpool, 4 in Bolton, 3 in Preston, and 3 in Leeds. The fatal cases of infantile diarrhœa, which had declined from 58 to 47 in the three preceding weeks, rose to 67 last week, and of this number 25 were registered in London, 5 in Liverpool, 4 in Birmingham, 4 in Manchester, 3 in Stoke-on-Trent, and 3 in Salford. The deaths attributed to measles, which had been 69, 64, and 72 in the three previous weeks, declined to 63 last week; the highest annual death-rates from this disease were 1·4 in Oldham, 1·8 in Reading, 2·1 in Warrington, and 2·5 in York. The 21 fatal cases of scarlet fever last week were equal to the average in the four preceding weeks, and included 2 in each of the following towns: Coventry, Liverpool, Salford, Barnsley, and Newcastle-on-Tyne. The deaths referred to enteric fever, which had been 20, 17, and 19 in the three preceding weeks, declined last week to 13, of which 4 were registered in Manchester and 2 in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily decreased from 2213 to 1562 in the 11 preceding weeks, had further declined to 1500 on Saturday last; 169 new cases of this disease were admitted to these institutions during the week, against 165, 162, and 158 in the three preceding weeks. These hospitals also contained on Saturday last 1199 cases of diphtheria, 340 of whooping-cough, 123 of measles, 49 of enteric fever, and 2 of small-pox. The 1538 deaths from all causes recorded in London were 162 in excess of the number in the previous week, and were equal to an annual death-rate of 17·7 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 290 to 333 in the three preceding weeks, further rose to 394 in the week under notice, and were 29 in excess of the number registered in the corresponding week of last year.

Of the 6278 deaths in the 94 large towns last week, 186 were referred to different forms of violence, and 452 were the subject of coroners' inquests. The causes of 62, or 1·0 per cent., of the deaths registered in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 57 other smaller towns. The 62 uncertified causes of death last week included 13 in Birmingham, 7 in Liverpool, 3 in London, and 3 in Warrington.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns having an estimated population of 2,182,400 persons in the middle of this year, 1069 births and 797 deaths were registered during the week ending Feb. 3rd. The annual rate of mortality in these towns, which had been 17·3 and 17·7 per 1000 in the two preceding weeks, further rose to 19·1 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual rate of mortality in these Scotch towns averaged 17·9 per 1000, and was 1·8 per 1000 above the mean rate recorded in the 94 large English towns during the same period. The annual death-rates in the several Scotch towns last week ranged from 7·5 in Motherwell, 9·0 in Clydebank, and 11·0 in Leith, to 22·7 in Dundee and in Greenock, and 23·3 in Ayr.

The 797 deaths from all causes were 57 in excess of the number in the previous week, and included 100 which were referred to the principal epidemic diseases, against 103 and 89 in the two preceding weeks. Of these 100 deaths, 55 resulted from measles, 14 from whooping-cough, 13 from infantile diarrhœal diseases, 12 from diphtheria, 5 from scarlet fever, and 1 from typhus fever, but not one from enteric fever or from small-pox. These 100 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·4 per 1000, or 1·2 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had been 41, 56, and 39 in the three preceding weeks, rose to 55 last week, of which number 43 were recorded in Glasgow, 4 in Greenock, 2 in Edinburgh, and 2 in Aberdeen. The deaths resulting from whooping-cough, which had been 18 in each of the two preceding weeks, declined last week to 14; 3 deaths were registered in Glasgow, 3 in Aberdeen, 2 in Greenock, and 2 in Kirkcaldy. The deaths of infants referred to diarrhœal diseases, which had been 9 and 11 in the two preceding weeks, rose to 13 last week, and comprised 8 in Glasgow, 3 in Dundee, and 2 in Leith. The 12 fatal cases of diphtheria were equal to the average in the four preceding weeks, and included 4 in Glasgow and 4 in Edinburgh. The 5 deaths referred to scarlet fever were equal to the average in the two preceding weeks, and included 2 deaths in Glasgow. The fatal case of typhus occurred at Motherwell.

The deaths referred to diseases of the respiratory system, which had been 120 and 133 in the two preceding weeks, further rose to 144 in the week under notice; and 31 deaths resulted from different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 653 births and 545 deaths were registered during the week ending Feb. 3rd. The annual rate of mortality in these towns, which had increased from 18·0 to 22·3 per 1000 in the five preceding weeks, further rose to 24·6 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in the 22 Irish towns averaged 21·5 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 16·1, while in the 18 Scotch towns it was equal to 17·9 per 1000. The annual death-rates in the several Irish towns were equal to 22·4 in Dublin (against 17·7 in London), 31·1 in Belfast, 19·7 in Cork, 12·7 in Londonderry, 25·8 in Limerick, and 15·2 in Waterford; while in the 16 smallest of these Irish towns the death-rate last week was equal to 21·0 per 1000.

The 545 deaths from all causes in the 22 Irish towns were 50 in excess of the number in the previous week, and included 31 which were referred to the principal epidemic diseases, against 41 and 30 in the two preceding weeks; of these 31 deaths, 15 resulted from whooping-cough, 7 from diarrhœal diseases, 3 from scarlet fever, 3 from diphtheria, 2 from measles, and 1 from enteric fever, but not one from small-pox. These 31 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·4 per 1000; the death-rate from these diseases did not exceed 1·2 in the large English towns, while in the Scotch towns it was equal to 2·4 per 1000. The deaths attributed to whooping-cough, which had been 19 and 15 in the two preceding weeks, were again 15 last week, and included 14 in Belfast and 1 in Dublin. The deaths referred to diarrhœal diseases, which had been 11 and 5 in the two preceding weeks, were 7 last week, all but one of which related to infants under two years of age; 3 deaths occurred in Dublin and 3 in Belfast. The 3 fatal cases of scarlet fever, 2 of which were recorded in Dublin, were equal to the average in the four preceding weeks. The deaths referred to diphtheria, which had been three in each of the three preceding weeks, were again 3 last week, and included 2 in Dublin. The 2 fatal cases of measles and that of enteric fever were all registered in Dublin.

The deaths referred to diseases of the respiratory system, which had steadily increased from 83 to 152 in the six preceding weeks, further rose to 184 last week. Of the 545 deaths from all causes in the 22 Irish towns, 145, or 27 per cent., occurred in public institutions, and 10 resulted from different forms of violence. The causes of 16, or 2·9 per cent., of the total deaths in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 English towns the proportion of uncertified causes of death last week did not exceed 1·0 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Surgeon-General Christopher Pearson has been placed on the Retired List at his own request (dated Feb. 2nd, 1912).

The following appointment has been notified :—Staff-Surgeon: A. R. Thomas to the *Excellent*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant James R. Hill is transferred to the Reserve of Officers under the provisions of Article 632, Royal Warrant for Pay and Promotion, 1909 (dated Jan. 30th, 1912).

Surgeon-General A. T. Sloggett, C.B., C.M.G., Principal Medical Officer, His Majesty's Forces in India, has been appointed Honorary Surgeon to the King. Surgeon-General J. G. MacNeece, C.B., has been appointed Principal Medical Officer of the Sixth (Poona) Division. Surgeon-General T. M. Corker has taken up duty as Principal Medical Officer of the Eighth (Lucknow) Division. Colonel W. W. Pike, D.S.O., has taken up duty as Principal Medical Officer of the Bombay Brigade.

Lieutenant-Colonel R. Kirkpatrick has joined at Cairo. Lieutenant-Colonel J. S. Green has been appointed to command the Station Hospital at Bangalore. Lieutenant-Colonel R. W. Wright has been posted to Fyzabad in charge of the Station Hospital. Lieutenant-Colonel T. McCulloch has taken over charge of the Medical Division at the Royal Victoria Hospital, Netley. Lieutenant-Colonel C. R. Elliott has been transferred from Lahore to Jhansi and appointed to command the Station Hospital. Lieutenant-Colonel B. M. Skinner, M.V.O., has been detailed as Senior Medical Officer in charge of the transport ss. *Rewa*, leaving Karachi for Southampton on Feb. 14th. Lieutenant-Colonel L. T. M. Nash will take charge of the Military Hospital, Hounslow.

Major F. G. Richards has been ordered to join in Ireland on March 10th and will be posted to the Cork District. Major T. H. J. C. Goodwin, D.S.O., has taken up duty at Devonport. Major W. H. S. Nickerson, V.C., has been transferred from Cherat to the Station Hospital at Peshawar. Major F. J. C. Heffernan has been posted to the Fifth (Mhow) Division. Major G. S. Crawford has joined for duty in the Dublin District. Major L. P. Moore has embarked for a tour of duty in India. Major W. P. Gwynn has taken up duty at Karachi. Major E. W. Slayter has been transferred from Bellary to Mount Abu and appointed to command the Station Hospital. Major St. J. B. Killery has been appointed to the Northern Command. Major J. M. Sloan, D.S.O., has taken up duty in India. Major G. St. C. Thom has been transferred from Murree to the Station Hospital at Rawal Pindi. Major R. H. Lloyd has embarked for a tour of service in India. Major R. J. Blackham has taken up duty at Peshawar. Major D. Harvey has joined for special duty with the Sleeping Sickness Commission in Nyasaland. Major E. P. Connolly has embarked for a tour of service in India.

Captain E. T. Potts has been posted to Ireland for duty in the Dublin District. Captain N. Low has been selected for attachment to the Belfast University Contingent of the Senior Division, Officers Training Corps. Captain H. C. Winckworth has been selected for appointment as Specialist in Advanced Operative Surgery to the Royal Herbert Hospital at Woolwich, in succession to Captain A. J. Williamson, who has embarked for a tour of service in the Straits Settlements. Captain G. W. W. Ware has been posted to the Southern Command. Captain R. L. V. Foster, from Devonport, has taken up duty at the Military Hospital, Crown Hill. Captain E. M. Pennefather has been transferred from Fermoy to Fethard. Captain C. E. L. Harding has taken up duty at the Station Hospital, Quetta. Captain H. H. A. Emerson has been transferred from Limerick to Derby and appointed Adjutant at the Royal Army Medical Corps School of Instruction of the North Midland Division. Captain M. C. Wetherell has joined for duty at Kildare. Captain J. C. L. Hingston has been appointed to the Station Hospital at Wellington. The following Captains have been posted to the Irish Command: E. W. Powell, O. Ievers, C. E. W. S. Fawcett, V. H. Symons, and M. J. Cromie.

INDIAN MEDICAL SERVICE.

Colonel C. F. Willis, C.B., has taken over duty as Principal Medical Officer of the Ninth (Secunderabad) Division of the Southern Army in India. Colonel R. W. S. Lyons has arrived home on leave of absence from India. Lieutenant-Colonel C. F. Fearnside has been selected for appointment as Superintendent of the Central Jail at Rajahmundry. Lieutenant-Colonel R. Bird, C.I.E., has taken up duty as Professor of Surgery at the Medical College, Calcutta, and Surgeon to the Medical College Hospital, vice Major E. Owen Thurston.

Major C. C. Murison has been appointed Superintendent of the Lunatic Hospital at Matheran, in succession to Major E. F. G. Tucker. The services of Major V. H. Roberts have been placed temporarily at the disposal of the Chief Commissioner of the Central Provinces. Major F. H. Watling has been selected to officiate as Superintendent of the Central Jail at Buxar during the leave of absence of Captain W. Gillitt.

The services of Captain N. H. Hume have been placed at the disposal of the Government of Eastern Bengal and Assam while that officer officiates as Civil Surgeon of Jalpaiguri. Captain K. S. Singh has been appointed Plague Medical Officer at Karnal. The services of Captain J. G. G. Swan have been placed permanently at the disposal of the Punjab Government. Captain A. W. C. Young has taken up duty as Specialist in the Prevention of Disease at Bannu, and has been appointed in charge of the Bacteriological Research Laboratory at Brigade Headquarters. Captain E. H. B. Stanley has arrived home on leave of absence from India. Captain P. Heffernan has been appointed Lecturer on Mental Diseases at the Medical College, Madras, and Superintendent of the Madras Lunatic Asylum. Captain W. W. Jendwine, medical officer of the 27th Punjabis at Alipore, has been appointed to Rawal Pindi as Plague Medical Officer. Captain D. M. C. Church has been granted leave of absence home for one year from India. Captain W. D. H. Stevenson has been appointed to the Bacteriological Department under the Sanitary Commissioner with the Government of India. Captain R. T. Wells, officiating civil surgeon at Dera Ghazi Khan, has been appointed Plague Medical Officer at Rotak, vice Captain S. B. Mehta, whose services have been placed at the disposal of the Government of India for employment in the Department of Education. Captain S. H. Lee Abbott, civil surgeon at Dalhousie, has been transferred to hold Civil Medical Charge at Ferozepore. Captain H. B. Steen, officiating first resident surgeon in the Presidency General Hospital, Calcutta, has been appointed to act as Surgeon-Superintendent of the hospital during the absence on privilege leave of Lieutenant-Colonel H. W. Pilgrim. Captain K. G. Ghorpurey has been appointed to officiate as Second-class Civil Surgeon at Aden during the absence on leave of Lieutenant-Colonel S. E. Prall.

Lieutenant G. G. James has been selected for appointment as Assistant to the Chief Quarantine Medical Officer in the Persian Gulf. Lieutenant A. L. Sheppard has been appointed to officiate as Officer in Medical Charge of the 122nd Rajputana Infantry. Lieutenant E. S. Goss has been placed under orders to embark for India. Lieutenant H. Stott has been appointed Specialist in Midwifery and Diseases of Women and Children, Burma Division.

ARMY HEADQUARTER STAFF IN INDIA.

The following appointments have been made:—Surgeon-General A. T. Sloggett, C.B., C.M.G., Army Medical Service, vice Surgeon-General Sir W. F. Trevor, K.C.S.I., C.B., M.B., Army Medical Service, to be Principal Medical Officer, His Majesty's Forces in India (dated Dec. 31st, 1911). Colonel H. Hendley, Indian Medical Service, vice Colonel D. ffrench-Mullen, Indian Medical Service, to be Deputy Principal Medical Officer, His Majesty's Forces in India (dated August 8th, 1911).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Yorkshire Mounted Brigade Field Ambulance, Royal Army Medical Corps: Percy Kingsley Steele to be Lieutenant (dated Oct. 6th, 1911).

4th Northern General Hospital, Royal Army Medical Corps: Charles John Coleman to be Captain (dated Dec. 15th, 1911).

DEATHS IN THE SERVICES.

Brigade-Surgeon Henry Elmsley Busteed, C.I.E., late I.M.S., in his seventy-ninth year. He received a commission in the service of the East India Company in 1855 and was a medical officer with the Horse Artillery in the mutiny of 1857-58. For his services at Cawnpore and Lucknow he received the medal with clasp. In 1865 he was appointed

assistant assay master of the Madras Mint, and was subsequently appointed to the Bombay Mint in a similar capacity. In 1872 he was appointed assay master at Calcutta and retired in 1886, in which year he received the decoration of C.I.E. While at Calcutta he collected the materials for "Echoes of Calcutta," a well-known standard work on the history of Calcutta.

Sir J. Porter, Director-General of the Medical Department of the Navy, inspected the medical establishment of Plymouth Naval Station on Jan. 31st.

Fleet-Surgeon Robert Hill, M.V.O., of the *Medina*, has on the return of the King and Queen from India been advanced to C.V.O.

Correspondence.

"Audi alteram partem."

GUARDIANS AND DISSECTION.

To the Editor of THE LANCET.

SIR,—The report of the meeting of the Southwark board of guardians which you publish has greatly interested me. My letter to the chairman seems to have been fairly quoted, and I have nothing to withdraw or excuse in it. The point is that we cannot treat the human body without knowing its structure, and we cannot learn its structure without examining the dead. Put in another way, we cannot learn to operate for the prolongation of life and the relief of suffering without practising on the dead, unless we are to practise on the living. I view the action of the important board of Southwark guardians with the greatest apprehension, since it is sure to be followed, as Mr. Hills hopes it will, by other boards. It now becomes our duty to decide whether we shall continue to keep in the background and watch our supply diminishing year by year, as it is doing, or whether we should not rather ask every thinking man to consider whether it is right to sacrifice lives and relief from suffering to a kindly sentimentalism.

Is the benefit gained by allowing unclaimed dead bodies to decompose naturally instead of being permanently embalmed and reverently dissected before being buried with due religious rites enough to set against the loss of the surgeon's skill when an instant operation is necessary in order to save some valuable life? I submit that we have no moral right to allow a single breadwinner to die or a single child to suffer unrelieved even if the alternative is the examination after death of every man who dies in the kingdom, be he duke, anatomist, Poor-law guardian, or pauper.

I can already feel that, while we are trying to educate those who have the charge of the poor in these elementary facts of medical knowledge, anatomists will have a very bad time of it, but we must face all that and hope for the help of those who are alive to the great responsibility which a guardianship of the poor entails. I have said nothing about the scientific side of the question. Of course we want to know not only where all the parts of the body are, but why they are as they are. It is quite arguable that a sentimental objection to dissection might be fairly set against this, but I have never yet heard any attempt to justify a refusal to allow the surgeon, who willingly gives his best skill to the poor in their need, to use the only means on earth to gain that skill.

I am, Sir, yours faithfully,

F. G. PARSONS, F.R.C.S. Eng.,
Lecturer on Anatomy at St. Thomas's Hospital and at the School of Medicine for Women.

St. Thomas's Hospital Medical School, S.E., Feb. 2nd, 1912.

*** The paragraph to which Mr. Parsons refers will be found on p. 408 of this issue of THE LANCET. We drew Mr. Parsons's attention to it.—ED. L.

THE EXTRACTION OF CATARACT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 29th, 1911, appears an article by Mr. H. L. Eason on the Extraction of Cataract. What directly concerns me in that article I here explain. On the basis of the rest of his article I hope to contribute matter of interest to the profession at a later date.

In Mr. Eason's article he, like a number of others in the British medical press, reviews 23 cataract operations performed by me in February, 1909, in Major Kilkelly's hospital, Bombay, as published in the *Indian Medical Gazette*, May, 1910, as if I had never questioned those results. By some peculiar accident ophthalmic writers in the British medical press seem only to have read the above-quoted number of the *Indian Medical Gazette* and the number of the *Ophthalmic Record* in which the same paper by Major Kilkelly appeared, and seem not to have read the remainder of the controversy in both journals. In fairness to your readers I ask you to publish the following *résumé* of that controversy. (The whole of the controversy can be seen in full by anyone who consults the *Indian Medical Gazettes* of 1910 and 1911, or the April number of the *Ophthalmic Record* of Chicago, 1911).

While at the Bombay Medical Congress in February, 1909, at the urgent request of Major P. P. Kilkelly, I.M.S., I performed 23 intracapsular extractions in his hospital and left by the next train. At the time of operation I entered the details of the operation on the bed-head tickets of these patients. I heard no more of the cases until I saw them reported by Major Kilkelly in the May number of the *Indian Medical Gazette* of 1910. My permission was not asked before the publication of these cases, nor was any information given me concerning them before the publication of the results. I was not invited down to Bombay to see and report on them myself. About the same time Dr. Pontius published notes of these same cases in *North-West Medicine*, U.S.A. In a succeeding number of the *Indian Medical Gazette* as a part of this controversy Major Kilkelly reported one side of a purely private case of mine done at Amritsar, Punjab, without consulting me and reported it incorrectly. The case was a failure, and he reported it as of "general interest," implying that it was in harmony with the Bombay cases—that such was the usual result of my cases, and that I knew nothing of the after-result of my cases. However, I was able to publish the whole of the case, putting a very different construction on the result. Dr. Pontius, with Major Kilkelly's permission (not having asked mine), examined the famous Bombay cases. When I put Dr. Pontius's facts as regards gross lesions alongside with Major Kilkelly's facts as regards the same lesions they very much disagreed in nearly every detail, even to the number of cases purporting to be mine (Dr. Pontius reported on 24 cases; I had operated on 23). I asked Major Kilkelly for the loan of the bed-head tickets to see my own entries on them, as both these surgeons had recorded more capsules left behind than were entered on the bed-head tickets. He declined to lend them to me, stating that he did not see "what useful purpose it would serve."

The results in themselves were utterly unintelligible to me, and when I put the facts of Dr. Pontius and of Major Kilkelly alongside of one another the only conclusion I could draw from the discrepancies was that these two surgeons could not have examined the same cases, but that the failures of Major Kilkelly's hospital had been paraded for him and for Dr. Pontius and been put to my charge. This charge I made in the controversy and no attempt has been made to meet it, and no attempt can be made to meet it while Major Kilkelly's facts and Dr. Pontius's facts stand. I consequently cannot understand how any fair-minded man can quote the results published by Major Kilkelly as having any bearing on intracapsular extraction.

I am, Sir, yours faithfully,

HENRY SMITH, M.D., M.Ch.,
Lieutenant-Colonel, I.M.S.

Amritsar, Jan. 15th, 1912.

THE COMBINED WHOLE-TIME MEDICAL OFFICER.

To the Editor of THE LANCET.

SIR,—Recently the *Western Daily Mercury* reported the proceedings of a joint meeting of the St. Austell board of guardians and the rural district council to consider the appointment of a medical gentleman to carry out the combined duties of medical officer of health, medical officer to the union workhouse, and also No. 7 District. A suggestion was also made that the office of public vaccinator should be included as well. After a discussion the matter was adjourned for a month, a committee being appointed to discuss the various sugges ted schemes.

It is proposed to pay a salary of £400 per annum to a medical gentleman, who presumably will have to devote the

whole of his time to his "official duties." The combined appointments are as follows: Medical officer to the union workhouse, £35; medical officer to the union district No. 7, £30; probable fees, £10; medical officer to the union cottage homes, £5; medical officer to the rural district, £270; and medical officer to the urban district, £70. We hear on good authority that the expense of conveyance, drugs, &c., will fall on the holder of this appointment.

The local medical men have protested against the injustice of including in the office of medical officer of health the duties which are performed by other medical men resident in the district, and were supported by at least two of the members who saw the danger of some of the work being neglected. Our main purpose, however, in writing this letter is to point out to the profession the grave danger they would be placed in by the creation of a medical bureaucracy, especially an inadequately paid one. These officials will be under the control, either directly or indirectly, of the Government. A sufficient number of them will in time become a sort of Government medical reserve to be employed under the Insurance and other Acts on terms which the more independent practitioner would refuse, a position which we trust no medical man will accept.

The case illustrates the points which were urged by many speakers at the Joint Medical Officers Associations' dinner, and shows the urgent necessity of all medical men who hold official appointments joining their respective associations, so that some joint action may be authoritatively taken in view of the increasing number of local bodies who are seeking to make these ominous appointments on the spurious ground of so-called economy.—We are, Sir, yours faithfully,

RASHELL DAVISON,
Chairman of Council, Association of Medical Officers of Health.
D. A. BELILIOS,
Honorary Secretary, Association of Medical Officers of Health.
New Malden, Feb. 6th, 1912.

KING EDWARD'S HOSPITAL FUND AND THE EVELINA HOSPITAL.

To the Editor of THE LANCET.

SIR,—I am gratified to notice that in THE LANCET of Jan. 27th (p. 242) you have been good enough to call attention to the difference of opinion between the King's Fund and the authorities of this hospital, and take this opportunity of thanking you for so doing.

Your article is, however, not quite accurate in one respect, and I shall be extremely obliged if, in justice to my committee, you will point out that, although the King's Fund insisted on an inquiry officer being appointed, their distribution committee have given absolutely nothing to meet the outlay incurred by having that official and establishing her department on a proper basis, the total cost of which, as stated in my letter to the *Times*, is over £200 a year.

My committee feel that the King's Fund have acted with some want of consideration for the hospital throughout the whole of this business, as the grant of £150 made at the end of 1910 was the amount usually allotted to this institution before the appointment of an inquiry officer was required. When my committee complied with the request that an inquiry officer be appointed, it was quite expected that the King's Fund would meet certainly a considerable proportion of the cost, in addition to the usual grant.

I am, Sir, yours faithfully,

D. MALCOLM SCOTT,
Jan. 31st, 1912. Chairman of the Committee of Management.

THE ACETONE-WRIGHT METHOD OF LEUCOCYTE COUNTING.

To the Editor of THE LANCET.

SIR,—Not long ago I sent to THE LANCET[1] an account of a method of absolute and differential white cell counting in one operation. Further experience of this method enables me to add the following remarks.

1. It is better to use a 1 c.c. pipette graduated in 1/100ths for measuring the various constituents instead of a graduated cylindrical vessel. With a pipette the proportions of acetone and water should be 2 to 13 instead of 3 to 12. I attribute this difference to the different shapes of water and acetone surfaces in narrow cylinders.

2. For convenience the acetone and water may be kept as a stock solution of 13 per cent. acetone to which 20–25 per cent. of Wright's stain (diluted four-fifths with methyl alcohol) is added just before use. The optimum quantity varies with the blood, the dilution, and the time elapsing before counting it. The results seem to be not quite so good as those given by freshly prepared solutions.

3. Much the best, simplest, and cheapest method is to mix the Wright's stain and acetone in a stock solution. The mixture is made thus. Grind up one soloid of Wright's stain in a glass mortar with successive quantities of methyl alcohol; pour each quantity into a glass measure, allowing a little while for sedimentation in the mortar. When 10 c.c. are in the measure again allow a little while for sedimentation, and then pour it into a tall, narrow, one-ounce bottle and cork it well. Then treat the residue in the mortar in exactly the same way with acetone till 10 c.c. are made up. Add this to the stain in the bottle, and then add direct 5 c.c. of methyl alcohol. There should be no precipitate, and this apparently keeps indefinitely if well corked.

This preparation may be used both for counting with a hæmocytometer and for staining films. With the hæmocytometer it is used as follows: Measure 0·3 c c. of distilled water and 0·1 c.c. of this mixture into a small cylindrical vessel of such a size as to let a 1 in 10 pipette reach to the bottom. Cork at once and shake well. Using a 1 in 10 pipette, dilute the blood 1 in 10 or 1 in 20. Draw up the fluid quickly till the bulb is nearly full, then hold pipette and cylinder horizontally and fill to the mark. Thus it is possible to make an absolutely exact dilution quite easily. Still holding the pipette horizontal, remove the cylinder, and cover first the point and then the other end of the pipette with thumb and finger and shake thoroughly, still holding it horizontal. The cover-glass should be put on the drop as quickly as possible. The method has, of course, all the disadvantages of the 1 in 10 pipette methods, but if the rules be adhered to, to base an absolute count on not less than 100 cells and a differential on 300 cells, absolute accuracy, as checked by films and Toisson's method, may be obtained in one-tenth of the time. If the cover-glass is put on smartly the distribution of the cells is quite even, but it is perhaps safer to visit equally all quadrants of the disc. I usually follow along the square which is contained by the disc in making a differential count, and count three of the large squares in a Thoma-Zappert slide for the absolute count. For rough estimation the small-squared area in two drops will give approximate results, both absolute and differential. In ordinary blood this area in each drop will contain 40 cells if 1 in 20 dilution is used. (The quantity of stain suggested is usually enough to fill a 1 in 10 counter and leave a little. For a 1 in 100 counter 0·8 to 1·0 c.c. must be made up.)

This "Peking modification" stains films quickly and well, but the usual method must be altered. Cover the film with stain for 20 or 30 seconds, then add an equal quantity of distilled water and mix well. Leave this for one minute, then pour it off, but *do not wash it off*. Dry the film over a flame, and then wash in distilled water; one dash of water from a test-tube is enough. The stain is very clear, the blue is a royal blue. The process takes two to two and a half minutes only and is very economical. Since acetone is added it seems unnecessary to use the very costly acetone-free methyl alcohol, but ordinary methyl alcohol may, perhaps, contain other undesirable impurities. I have no experience of this, nor do I know whether the malarial parasite can be stained in this way, but I see no reason to doubt it.

The further problem of combining red, white, and differential counts in one operation has been solved by Schüffner.[2] His formulæ as reported in the *Medical Officer Supplement* are:—Solution A: Sodium chloride, 4 grammes; phenol, 3 grammes; borax, 0·1 gramme; formalin, 1 c.c.; and distilled water to 1 litre. Solution B: Methylene blue, 1 gramme; potass. hydrate, 0·1 gramme; and distilled water to 100 c.c. For use add two drops of B to 10 c.c. of A.

It is certainly possible with this stain to make an absolutely accurate white and differential count 12 minutes after taking the blood; the staining does not show clearly sooner.

[1] THE LANCET, Jan. 6th, 1912, p. 20.

[2] Münchener Medizinische Wochenschrift, 1911, p. 1495.

The eosinophils are quite easy to recognise, and the rest are well stained. But whether it be a peculiarity of Peking blood or a misprint in the report, I have found the solution made up as above distinctly hypotonic, and the red cells have been destroyed to the extent of 5 to 20 per cent. in ten minutes. To avoid this I have added 0·5 gramme of sodium chloride, and get satisfactory red cell counts, but the polymorphonuclears do not stain so clearly; the stain of some becomes diffuse and others lose it altogether in 30 minutes. This laking may be a local peculiarity, for the blood of both natives and foreigners here has special features, but it is worth mentioning as there may be no other indication than a gradual reduction in the count in successive drops or an occasional "cell ghost" with the hæmoglobin in a corner. If either of these things occur, in all probability at least 10 per cent. of cells have been already destroyed. Therefore, although this method is exceedingly handy and quick when a general idea of the blood is required, I would strongly advise that anyone who uses it should compare his results with those obtained by Toisson's fluid several times before trusting to it altogether. Even with the extra sodium chloride a little laking begins to occur after an hour or so, but for immediate use the results are quite trustworthy. I am, Sir, yours faithfully,

R. A. P. HILL.

Union Medical College, Peking, China, Dec. 12th, 1911.

THE PRACTICE OF MEDICINE IN BRITISH COLUMBIA.

To the Editor of THE LANCET.

SIR,—Dr. G. Gibson, in THE LANCET of Dec. 16th, 1911, sounds a timely note of warning as regards the conditions necessary for practice in British Columbia. Medical men in the old country are being tempted to buy fruit farms in the province, and it is important that they should know that their British qualifications do not entitle them to practise out here. The examination, mereover, which they have to pass before being allowed to register is not a mere formality. Even a well-informed practitioner, unless he had done a few months' reading before the examination, might find that he had failed to satisfy the examiners. For the examination is a very comprehensive one, and includes many subjects which we are apt to put aside after our student days are over.

As regards the chances of practice, they are not as good as might be imagined. It is true British Columbia is a highly prosperous country with a great future ahead of it. But it is as yet but thinly populated outside of the towns. All openings there may be are rapidly filled by medical graduates from the Canadian schools. At present there are nearly 600 names on the Medical Register, and most of these men are in active practice. The population of the province, on the other hand, barely amounts to 400,000 (386,000 according to the last census taken in May, 1911). In the city of Vancouver, with a population of 130,000, there are over 150 registered practitioners. The number of medical men out here is greater *per capita* than it is in England. It should, however, be stated that there is little or no poverty, and there are few who cannot afford to pay for medical attendance.

Dr. Gibson is, I am afraid, a little generous when he puts down $1500 (£300) as what a new-comer might reasonably expect to make during his first year in Vancouver. This, moreover, only states one side of the question. Living out here, it should be mentioned, is from 75 to 100 per cent. higher than in England. It is also the custom here for medical men to have an office in the business section where rent is necessarily very high. If a man is married, and unless his wife is prepared to do all the household work, he will find the cost of servants a very heavy item. A general servant costs from £5 to £7 per month, while it is difficult to obtain a cook (usually Chinese) at less than £10 a month. As regards special work, such as eye, ear, throat, and nose, the field is fully occupied, there being at least a dozen men engaged in these specialties.

British Columbia offers, as Dr. Gibson says, better chances, especially to the younger men, than does the old country. But, as he wisely remarks, it is a serious mistake to think that all one has to do is "to stick up one's brass plate and the patients will come pouring in." It would not be wise for anyone who intends starting in one of the coast cities (Vancouver and Victoria) to have less than a capital of £200 after arrival here. He will find that he requires that amount and more to defray preliminary expenses as well as cost of living during the time that must necessarily elapse before he will get both ends to meet from the proceeds of his practice.

I am, Sir, yours faithfully,

F. L. DE VERTEUIL, M.D. Edin., M.R.C.S. Eng.,
Surgeon R.N. (retired).

Vancouver, Jan. 3rd, 1912.

PSYCHOTHERAPY AND GENERAL MEDICINE.

To the Editor of THE LANCET.

SIR,—May I have space for a few remarks suggested by Dr. Branson's letter in to-day's LANCET? I have had some considerable experience of the practice of hypnotic suggestion, and hope that this will be a sufficient excuse. 1. In Dr. Branson's method he attempts to influence the patient's judgment, and in just the same way I try for the same result. I do not ask the patient to "surrender his judgment." As a matter of fact, the patient will often refuse a suggestion which is against his reason. The hypnosis only heightens his suggestibility and enables me to persuade him to use his own bodily powers on his own behalf. 2. The reasoning power of the patient in a state of hypnosis is not by any means entirely suspended. I have often argued with the patient about the cause of a symptom, and have brought him or her to reason with excellent results. 3. The patients who are amenable to hypnotic suggestion are not "those who are hovering between the neurologist and the alienist." These are the least amenable of any. Those whom Dr. Branson uses his "rational psychotherapy" upon are the best subjects for hypnotic suggestion. In fact, what Dr. Branson calls "rational psychotherapy" is really suggestion without the aid of hypnosis, its most valuable ally. I feel sure that if Dr. Branson could so far put aside his personal prejudice against hypnotic suggestion as to make a study of it he would very soon realise the truth of what I state and that his prejudice would rapidly disappear.

I am moved to make these remarks by the feeling that such a valuable weapon in our armoury as hypnotic suggestion should not be decried upon merely theoretical objections, which, practical experience shows, have no real basis. I am, Sir, yours faithfully,

Westcliff-on-Sea, Feb. 3rd, 1912. JAMES B. TOMBLESON.

THE ADMISSION OF VENEREAL CASES TO GENERAL HOSPITALS.

To the Editor of THE LANCET.

SIR,—I have read with much interest a letter with the above heading and signed "A Hospital Matron" which was inserted in THE LANCET of Jan. 27th. I have also read the paper on Venereal Disease, its Present and Future, in THE LANCET of Dec. 9th and 16th, 1911, written by Dr. Douglas White and Lieutenant-Colonel C. H. Melville, R.A.M.C., as well as the leading article, entitled "The Racial Importance of Venereal Diseases," in your columns of Dec. 16th. In this article you yourself recommend the procedure suggested by the above authors, and which is so obnoxious to "A Hospital Matron": that "in every hospital there should be accommodation for the treatment of venereal cases, both as in-patients and as out-patients."

The writer of the letter bases her objection to this measure on the disturbing effect it might have on the susceptibilities of "the ordinary well brought up girl of from 20 to 25, the usual age at which probationers enter hospitals," and who "is ignorant of the existence of venereal disease and of the horrible consequences of contracting it," and who, therefore, "certainly should not be exposed under compulsion and in ignorance to such a vile contagion." But this seems to me hardly a valid plea to urge against admitting venereal cases into general hospitals. To begin with, they *are* admitted into many general hospitals every month in the year, though not into "special wards," and though not always labelled as such; and therefore apparently no exception is taken to their presence in the wards. I need only quote from an annual volume of Hospital Reports

I have at hand that contains a list of all the medical and surgical cases admitted during the year into a large London hospital. It so happens that nearly 20 years ago that same hospital decided to close its male and female "lock ward" with 22 beds, and this was converted into a general surgical ward. I was sister of that ward afterwards for three years, and many "specific" cases came in for operation. In the reports I note gonorrhœa, 3 cases; gumma, 1 case; tabes dorsalis, 24 cases; syphilis, 17 cases, and there are probably others.

As regards infection, every woman who takes up nursing or midwifery knows—or *ought* to know—what risks she runs, while her exposure to infection only differs in degree but not in kind from that of the medical men and students who attend infective cases. The contact with certain forms of venereal disease constitutes a very serious risk to all who enter the medical or nursing professions. But women may become midwifery pupils at an age before they are admitted to some of the large general hospitals, and in district work they are exposed to far greater danger of infection from gonorrhœal discharges and from handling infants exhibiting the external manifestations of congenital syphilis than they are likely to be exposed to in the wards of a general hospital.

A high degree of "nerve" and of moral courage is required to make an efficient type of nurse, but she also needs to carry about with her Charity's mantle. "A Hospital Matron" says very truly that "no real nursing can exist where the patient's personality is treated as non-existent and the area of disease alone is considered." But surely this is an argument all the other way. The disease and its etiology may inspire the nurse with "horror and repulsion," but if, at the same time, it induces her to feel nothing but "disgust for its victims," I think she would be wiser in choosing some calling that makes no claim on her human sympathies. The "intolerance of youth" is not permitted to those who nurse the sick. All of us who have worked in general hospitals have had occasion to nurse "police cases." But a patient is a patient, and so long as his physical disabilities require our skilful ministrations his entire dependence on us must appeal to our nursing instincts, and we take little or no count of his moral obliquities. Incidentally, I have known this attitude to have a very humanising effect on the "sinner." And with regard to the sinner who comes to us for bodily tending I think we would do well to remember how it was once said: "Neither do I condemn thee."

I am, Sir, yours faithfully,

Hamburg, Feb. 4th, 1912. EMILIA V. KANTHACK DE VOSS.

M. BERGSON'S "CREATIVE EVOLUTION": THE NERVOUS SYSTEM IN ORGANIC EVOLUTION

To the Editor o THE LANCET.

SIR,—M. Henri Bergson's new theory of organic evolution, as brought out in his work, "L'Évolution Créatrice," a translation of which into English by Mr. Arthur Mitchell appeared a short time ago,[1] is bound to have a wide influence on thinking men, since in the chaotic state of biology as regards the factors of evolution, and the complete abstention of biologists from taking an intelligent interest in Lamarckism, especially as modified by recent science, it offers to the thinking man the most plausible theory for the operations at work in organic evolution.

The leading criticism of M. Bergson as to the existing theories of evolution is that there is no indication in any of them of any factor which would make for coördination. He cites as an instance as regards natural selection one of the strongest arguments against it—viz., that it is impossible to conceive that variations occur in nature in such correlation with each other as to lead to modification dependent on the simultaneous appearance of variations in different parts of the organism—e.g., in the brain and the peripheral parts correlated therewith in the eye. And one of his strongest arguments indicative of purpose in evolution is that special organs become developed on a similar plan in organisms that had diverged from the stem at a comparatively early period in evolution—e.g., the eye of molluscs and of vertebrates, and also in the case of the sexual apparatus of animals and plants, as illustrating unity of purpose. M. Bergson is, of course, a teleologist, but it seems to me he makes his working out of the plan to depend on subsequent conditions which arise as progress is made. Back of all is the creative energy, which works upward in a definite way and always with a definite aim. Such a theory, as I have stated, will, no doubt, gain wide acceptance, since it postulates an initial purposeful force through which evolution has been carried on, and by which coördination is effected. Theologians will doubtless hail it as being in harmony with, and really an explanation, if an expansion of their special creation views; and as such they will accept it as a new stronghold—in their attempt to harmonise dogmatic theology with science—especially since it seemingly is based on scientific grounds.

It will be idle for biologists to belittle it, to attempt to brush it aside by sarcasm or put it down by weight of authority; they will have to sink differences and retrace their steps in order to learn why, and how, such a theory as M. Bergson's has apparently so much truth in its favour. And in doing so they will have to go back to the teaching of Lamarck, whose theory—misunderstood in the past—in the present day, with the light of modern scientific knowledge, can be made to explain not alone the apparent truth in M. Bergson's theory, but once and for all, by demonstrating the true factors at work, lay bare the foundation on which the true process of organic evolution has been built. The absence in all theories of evolution of any factor which makes for coördination in development, as I have stated, is the characteristic feature revealed in M. Bergson's work. On the contrary, in Lamarckism this coördination and correlation is made clear. How is this shown? By demonstrating that through the nervous system such a coördination is effected. It is due to the fact that the influence of the nervous system in organic evolution has hitherto been ignored by biologists that it is possible for a theory such as M. Bergson's to be advanced and apparently rendered acceptable to thinkers. Let us see how the nervous system has been developed, and let us learn how its influence has been operative all through the progress of evolution.

The simplest organism consists of one cell. The functions of this cell are: (1) division or propagation, (2) absorption or nourishment, and (3) irritability or protection as seen in motion. When two or more cells are united to form one organism we find the same three functions; but even so low down in the scale of life as the hydra we find that certain cells are more sensitive than others and are known as *neuro-musoular* cells. "It is important," states Professsor McFarland,[2] "to note that the purpose of the primitive nervous system seems to be to correlate external impressions with the movements directed towards the capture of food or escape from enemies." And in order to show that through the nervous system coördination is effected in evolution, in his chapter, "The Higher Organisms," he denotes the section on the development of the nervous system, *innervation and coördination.*

For the very lowest organisms there are certain conditions in the environment to which they react. These reactions are known as *tropisms*, and consist for the most part of reactions to heat, motion, and chemical action in a general way. As organisms rise higher the various reactions become specialised, and the special senses, foreshadowed at an early time, are gradually developed. As, however, the various diverging lines of advance seem to respond in a similar way, it would seem that following the adjustment of living protoplasm to the environment as regards light, heat, and other physical conditions, the need is the determining factor in all cases. Professor McFarland thus writes[3]: "The increasing structural complexity appears to be largely a matter of necessity"—i.e., for the satisfaction of the needs of the organism. To a physician the controlling and coördinating power of the nervous system must be clearly evident, since, as I have previously stated in your pages, he is capable of looking at the question from a standpoint of fuller knowledge than the pure biologist—a standpoint gained from a study of the organism from the unicellular, the beginning, to man, the final stage. In the gradual evolution through the nervous system we have a series of gradations somewhat different from the gradations

[1] THE LANCET, June 24th, 1911, p. 1710.

[2] Biology, General and Medical, p. 149.

[3] Ibid., p. 120.

assumed in natural selection, since each step forward is registered, as it were, by the nervous system, which controls and coördinates it, so that it is possible for each advance to be gradually transmitted as a higher and higher step is reached. And this is made possible since the need is a gradually increasing one, and is present in young and old and in both sexes, and is supplied through voluntary action. Hence each step is registered in the germ-plasm, or its developments, the germ, sperm, zygote, and embryo, and appears at birth as a variation.

In a review of M. Bergson's work, "Creative Evolution," in the columns of the *British Medical Journal*, the reviewer thus expresses himself as regards M. Bergson's theory in relation with that of Lamarck: "The resort to an internal principle of direction which M. Bergson considers indispensable appears to have suggested a return to the position of Lamarck, who somewhat naively attributed to the living being the faculty of modifying its organs by use or disuse, and of transmitting to its offspring the variations thus induced. But in the first place, this hypothesis leaves the variations of plants quite unexplained; in the second, the inheritance of acquired characters, if it ever occurs, must clearly be very exceptional. Moreover, granted its occurrence, the question at once arises, Was the new habit of purely somatic origin, or was it not based on an inborn tendency of germinal origin?" In this criticism of Lamarck the reviewer betrays a lamentable misapprehension of his theory. In the first place, Lamarck made a broad distinction between the modifying factors in plants and animals. As regards the former, he stated that the direct influences of the changing environment had a directly modifying influence, since plants become modified through their nutritive processes. That such is the case has been amply proved by Professor Henslow and many other eminent botanists, and again recently by Prince Krapotkin in the *Nineteenth Century and After*, his facts being drawn from the observations of experimenters in several different countries.

As regards animal life Lamarck *never* stated that animals have the power of modifying their organs directly through willing or desiring for such changes, leading to use or disuse of organs, as is maintained by biologists. What Lamarck did state was this: Owing to changes, climatic and otherwise, affecting their needs, animals, in order to sustain life, are forced to adopt new habits, to adopt new methods of satisfying their wants of food, &c. These new habits being forced through need on all the animals alike, and the new habits being voluntary in those with a nervous system, the results are registered on the germ-plasm and its developed stages, germ, sperm, zygote, and embryo. Hence the gradually acquired new habits, being permanent, and being forced on all, young and old, male and female, the organism is also gradually modified to suit the new conditions of life until full or relatively full adaptation is reached. Weismann, although at first basing his whole theory of evolution on the inviolability of the germ-plasm, was soon forced to recognise that no progress could be made thereby, since there could be nothing additionally acquired by which evolution could proceed; hence he was forced to admit the influence of the environment on the germ-plasm in order to account for adaptation. That is the position of Weismannism, on which Neo-Darwinism is based. But Lamarckians also recognise the influence of the environment on the germ-plasm, but whereas Weismann limits the influence solely to the germ-plasm, Lamarckians maintain that the influence is not so limited, that the same process by which the influence is made on the germ-plasm is extended, so that not alone is the germ-plasm modified but its various stages of development—the germ, sperm, zygote, and embryo—are similarly modified, and that the modifications produced appear at birth as innate characters or variations. Since the environment includes everything to which the organism can react, and since change in environment means change of reaction on the organism, it must be plain that when through unfavourable changes organisms are forced to adopt new methods of feeding—as when the giraffe, unable to procure nourishment through gradual failure of surface vegetation, is forced to take on the habit of eating the leaves of trees—it must be plain that the effects of new habits affect the organism, so that through transmission of the effect the various parts affected become more and more adapted to the new mode of life until full adaptation is reached. And the changes effected are in coördination with each other, since the effects of the new mode of procuring food, seeking protection, &c., are brought about through the nervous system.

That modification of function relatively quickly modifies the organ is well seen in John Hunter's experiment with a seagull. He took a gull accustomed to feed on soft food and fed it on grain for a year. At the expiration of the year he killed it, and found that the muscular structure of the stomach had been so markedly modified as to assume the appearance and consistency of a gizzard. Under the necessary circumstances such a change in character would be transmitted. Now what Lamarckians claim is this: When gradually climatic and other changes occur in the environment of animals (and there is clear evidence that such changes have continually taken place all over the surface of the earth) so as to affect unfavourably their needs for food, protection, &c., the animals must either (1) die out, (2) migrate to a more favourable environment, or (3) adopt new habits as regards feeding, &c., as in the case of the giraffe already mentioned. Now these new habits being gradually acquired, and being forced on all alike, the young and old, and on both sexes, and being voluntary—i.e., through the need or desire for food, &c.—the nervous system, governing not alone the germ-plasm but its developments, is also modified. As a result the various parts affected in the satisfaction of the needs become coördinated and correlated, as in the giraffe, in which not only are the head and neck elongated, but also the fore-quarters and to some extent the hind-quarters, as the result of the new habit of feeding on the leaves of trees. As it must be plain that the effects of the new habits are innate characters and thus capable of transmission, in process of time the parts involved in the new habits must gradually more and more approximate to full adaptation as we see them, so as to answer satisfactorily the needs of the animals. By that means of modification we are able to understand how slight gradations are brought about, since a new habit may at times only partially modify an organ.

The above explanation is altogether different from that held by biologists as regards Lamarckism and is one capable of making clear the whole *modus operandi* of organic evolution.

A fact which has evidently been lost sight of in postulating a creative force acting upwards and definitely, is that there are certain organisms living in the present day that have existed in their present forms from the very earliest periods, thus demonstrating that in their case at least the creative energy or *vis a tergo* did not work upwards in any direction. To postulate a force acting extrinsically on matter is to lose the full significance of evolution. This world is a physical one, but within its potentialities, I claim as my belief, is that of the evolution from physical conditions of a form of energy called "mind." Just as from the 32 pieces of the chess board games requiring the highest mentality may be evolved according to the correlation of the pieces on the board, so from the correlation of sensory impressions on the higher cerebral centres, mind or consciousness may be and is gradually evolved. Instinct is the result of the transmission of accumulated habit—mind or consciousness is the correlation of instincts; and in the process of evolution it is the gradual evolution of the nervous system crowned by the brain which renders possible, not alone the organism with its various organs subserving the needful functions, but the evolution from a minute mass of living protoplasm of man, with a mind capable of pronouncing an opinion on work which must have been designed by another and a higher yet similar mind.

In the above criticism of M. Bergson's theory I have not taken into consideration his differentiation of intellect as exhibited in man, from intuition in man and instinct as exhibited in the hymenoptera, since structural conditions through the nervous development can be made to account therefor.

I am, Sir, yours faithfully,

Bridgetown, Barbados, Nov. 29th, 1911. R. F. LICORISH, M.D.

SECURITY OF TENURE FOR THE MEDICAL OFFICER OF HEALTH.

To the Editor of THE LANCET.

SIR,—I was glad to read the sentiments expressed in your leading article on this subject in THE LANCET of Feb. 3rd. What has happened to members of the Public Health Service since the issue of "The Sanitary Officers (outside London) Order, 1910," has proved that I was none too pessimistic as to its benefits when I wrote an article thereon which was published in THE LANCET of Feb. 25th, 1911, p. 542.

Cases such as those at Claypole and Edmonton do not occur with sufficient frequency to attract the attention of the lay papers and their readers, although one case is enough to dishearten *all* medical officers of health subject to three months' notice, and quite sufficient to discourage them from displaying any energy or honesty in their work. If the general body of ratepayers only perfectly understood what the present chaotic state of the law means to the detriment of their families and themselves, there would soon be an insistent and persistent demand that the Local Government Board should without delay amend the Order so that the tenure of office of the medical officer of health should be the same as that of the doctors who attend sick paupers.

Of course, everyone interested in the public welfare welcomes the recent instances of the Board's firmness in dealing with corrupt councils, which firmness is more effectual in the case of a whole-time officer, because in his case the half salary repayable to his council is a considerable sum and not a mere trifle (say £10 to £25) as in Claypole, Yorks. But an amended or new Order giving security of tenure to medical officers of health *whose whole time is engaged in public health work* would relieve the Local Government Board of this unpleasant duty.

Loss of office is sad but not serious for a part-time officer, for he has his private practice still for maintenance of himself and family, whereas to a man whose livelihood is entirely dependent on his official salary dismissal (although without just cause) brings about his complete ruin, especially if he is (as at Edmonton) over 50 years of age and therefore shut out by age-limit from applying for 90 per cent. of the appointments that may fall vacant.

I am, Sir, yours faithfully,

Feb. 6th, 1912. ENERGY.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—In a letter published in THE LANCET of Jan. 20th I expressed an opinion that the present executive of the Association was too much in favour of the National Insurance Act, and only demurred to some of the medical provisions of that measure. I consider that opinion largely strengthened by the recent report of the Council to the members of the Association. Many of those who read carefully that—in my opinion—inaccurate and misleading document will have forced upon them a conviction that they who drafted and approved it must have views, to say the least, very different to those of a large number of the profession. There is no acknowledgment of error with regard to the Whitaker incident, although it has been so universally condemned by the profession that not even a representative meeting will be able to whitewash it. I do not wish, however, to re-open this subject. The sooner it is dead and buried the better, but I may instance its treatment in the report as evidence of how little the present executive care for outside professional opinion. No reasons are put forward stronger than those advanced in the inaccurate circular issued at the time, and approved at the last Council meeting. It would seem to be thought that weak and insufficient reasoning acquires strength and validity by frequent repetition.

Take, again, that portion of the report that the *Times* did us the honour to publish in its issue of the 3rd inst. The whole is a kind of appeal to the profession to accept the Act and work it for what it is worth, in spite of its admitted injustice to the profession. At the same time it suggests that if, notwithstanding the Council's good feelings towards it, certain conditions are not granted under the Act, it will itself advise the course it here condemns.

I take strong exception to some of the inaccurate and misleading statements. Speaking of the "suspension of medical benefit" (32): "It is only too probable that the great bulk of the insured would be quite content to receive a cash allowance which would enable them to join medical clubs of their own outside the Act, while the Friendly Societies would welcome it as practically restoring to them that full and complete control of their doctors which the Insurance Act had taken away." Not a word is said as to how many would utilise the money thus received in paying their private doctors' fees, as they do now, but it is gratuitously assumed the number would be very small. The suggestion that the "*great bulk*" would form "medical clubs of their own outside the Act" is, in my opinion, very misleading. "That the Friendly Societies would welcome it as practically restoring to them that full and complete control of their doctors which the Insurance Act had taken away" is, in addition, contradictory to previous official statements of the Association. It has over and over again been said that the Harmsworth amendment in reality gave back the control the Act was supposed to have withdrawn, and very few, with the exception of certain members of the Council, have ever regarded of the slightest good the modification of that amendment acquired by the Association at the latest stage of the measure, and which has been tabulated as one of the *gains* of the Association. There is no need to argue this point. The fact remains that in spite of this precious *gain* the representative meeting last November persisted in demanding the deletion of the Harmsworth amendment altogether, and the appeal sent up by the executive to the House of Lords amply proves this. "The last four lines of the subsection (15, 4) as finally amended in the House of Commons do, it is true, secure to a great extent free choice (?), *but in the opinion of the profession the whole subsection, even as amended, is undesirable in the public interest not less than that of the profession and should be deleted.*" If, then, the control of the doctors has been recovered by the Friendly Societies through the Harmsworth amendment, it is untrue to say that the suspension of medical benefit "would have the effect of practically restoring to them that full and complete control which the Insurance Act had taken away."

What, also, is to be thought of the following argument for the profession working the Act? "In short, suspension of medical benefit renders possible a vast extension of club practice for provident persons." If the profession accepts the working of the Act, and the panels are formed, a "vast extension of club practice" will not only be *possible*, but *certain*—a club practice far more degrading in my opinion than the present system, and far more deadly to the interests of the general practitioners of the country. After all, whatever the defects of the present system may be, it is in the hands of the profession at any time, if united, to reform it. But it will be otherwise when we have delivered ourselves up tied and bound in the meshes of this Act, to form a second-rate State Medical Service most injurious to our own interests, and of doubtful utility to the public.

I am, Sir, yours faithfully,

Feb. 3rd, 1912. MAJOR GREENWOOD.

To the Editor of THE LANCET.

SIR,—Why should a doctor be paid higher than a labourer? Each does work for the State to the limit of their abilities, and no man can do more. This is the socialistic argument. Everyone who has met Socialists has heard it scores of times, and it seems that Mr. Lloyd George has imbibed this particular idea, but he knows too much of the sturdy character of the British labourer to attempt to fix *his* income by Act of Parliament. He knows that there would at once be a strike, and that the labourers would hold together as one man, even though it meant a total suspension of income.

But that which he would never and could never have done in regard to the lower type of labour he has attempted to do to the higher, and so you have this idea not only fully carried out, but you have an extension of it, and a limit placed by Act of Parliament upon the income of the doctor which could never have been placed on the labourer The doctors have absolute power in their hands. Any man can be a labourer, but only trained men can be doctors. It takes many years to fit a doctor for his duties, but if the doctors stand shoulder to shoulder there is no Act of Parliament which can compel. It does seem absurd that all other people in the country are permitted freedom to sell their services at the highest price they can obtain according to the laws of supply and demand, but the doctors only should be specially selected to be excluded from this freedom.

If the medical profession know their own interests they will neither accept this Bill nor any amendment of it. There is one thing to fear, and that is, that if some new conditions beneficial to them are conceded they will be undermined gradually in the operation of the Bill, and that unless a determined stand is taken against it now we shall have the State

employing a staff of doctors at say, £150 to £200 a year, and the profession will sink to a lower level in Great Britain than in any other part of the world.

I am, Sir, yours faithfully,

ARTHUR E. BECK

King's Norton, Feb. 2nd, 1912. (Prospective candidate for Derby).

To the Editor of THE LANCET.

SIR,—The following views on the Recommendations of the Council of the British Medical Association, especially as regards the formation of an English Medical Insurance Council and of a National Medical Insurance Council, are shared by many medical men in Brighton and other districts. It is held that Recommendations 1, 2, and 3 should be omitted and that the following resolution be substituted:—

That the Council be instructed to notify H.M. Government through the Insurance Commissioners that the medical profession can take no share in the working of the Act until the six cardinal points are granted by law.

Recommendation 4 should be altered as follows:—

That the Council be instructed to make all necessary arrangements for assisting the Divisions and Branches in the appointment of provisional Medical Committees in every insurance area to safeguard the interests of the profession and to organise a national medical service under medical control.

Recommendation 5 should read:—

That the Council be instructed to take steps to organise the profession so as to secure that on and after July 1st, 1912, no person shall be able to secure medical attendance under a contract practice appointment held at lower rates than those which may be agreed upon as adequate by the Representatives for attendance upon insured persons.

Recommendation 6 should be altered to—

That an English Medical Insurance Council be formed from the British Medical Association and other medical bodies and a Joint National Medical Insurance Council for England, Scotland, Ireland, and Wales.

In conclusion, it is of vital importance that a meeting of English Representatives of the British Medical Association be held at once to exchange and focus opinions on their future action at the special Representative meeting on Feb. 20th. A similar course obtains in the groups and committees of M.P.'s in the House of Commons, and is perfectly fair and proper. It may be held that Recommendation 5 may mean the use of the "strike" weapon. Are we prepared for this? Is it humanly possible to call everyone out for such a purpose? What would be the consequences of failure? Would our *first* strike be likely to be successful? I think with good organisation we should win, and then we could present the public with a really efficient public medical service.

I am, Sir, yours faithfully,

Worthing, Feb. 6th, 1912. F. G. BUSHNELL.

To the Editor of THE LANCET.

SIR,—I have read all your leading articles on the Insurance Bill, and have been much impressed by the attitude of dignity and reserve you have taken up. For this reason I call your attention to a point which concerns more especially men like myself, the rank and file of country practitioners. My practice, and there are many others like it, is a very poor one, composed largely of club patients, the men being mostly in Friendly Societies, the women and children in personal medical clubs. Now, the Insurance Act cannot hurt us financially; it would probably benefit us. I am not a member of the British Medical Association; I have signed no pledge exploited by a journal, and have no intention of doing so. What line the best members of the profession decide is to be taken, that line I shall take—i.e., I shall stand by the profession. This remark was, however, made to me only yesterday by a large landowner and officer on the retired list: "It will be a great pity surely if 29½ thousand men try to wreck a measure designed for the national good because their pockets are touched." Now, Sir, the point I want to draw your attention to is this. Men like myself, who are trying under adverse circumstances to keep up the dignity of the practice of medicine and surgery, look to those above who have constituted themselves the champions of the profession to take their stand not only from a financial point. The fees of the consulting world are paid mostly as a matter of course; it is often the country practitioner who sees that they are paid promptly and without question. I think that consultants are hardly aware how difficult it is for the man in the country to maintain the professional standard. I express myself haltingly, I fear. What I am aiming at is, that in our differences with the Chancellor and his advisers we are making too much of the financial side, not enough of the fact that we are professional men like himself (only that the nation pays him a good salary and he has not to worry about ways and means), and that our services are no more to be exploited as the Government think fit than those of, say, members of the Bar. I am, Sir, yours faithfully,

EDWARD T. JONES, M.R.C.S. Eng.

Eastmeon, Hants, Feb. 5th, 1912.

To the Editor of THE LANCET.

SIR,—Is it not waste of time and money to hold a Representative meeting of the British Medical Association while we are in the dark as to the Commissioners' intentions, unless the intention of the meeting is to declare finally that we will not work the Act as it stands? Does the Council of the Association realise this? If the funds are so limited that the Commissioners cannot accede to our vital demand for adequate remuneration, why temporise further on side issues?

The Commissioners can, however, and conceivably would, suspend medical benefits in refractory areas or altogether, a result the Council appears to dread, as they consider this result would be extremely serious to the profession by rendering possible a vast extension of club practice for provident persons, and bad debts in the case of the improvident. To my mind this is a delusion. Some six million insurables are already in clubs, and it is practically certain that, as at present worked, this is not far from the clubable limit. Most of the medical officers would be unable, even if willing, to cope with a huge and sudden increase of membership.

At a crisis like this, with the state of feeling evidenced by the 26,000 signatures to the Association pledges, a large number of them would, I feel sure, be willing to fall in with the desires of the profession, as voiced by the Council, even to the extent of resigning their appointments. But this would not be necessary. They would simply be required to raise their terms to those declared equitable by the Council for working the Act. And does anyone believe they would hesitate to do so? Two or three thousand new medical officers might possibly be procured to work the Act at 4*s.* 6*d.* per head per annum, or at less than the Association rate, but to me it is quite clear that it would be utterly impossible to officer a vast extension of club practice, and there are nine millions to provide for. The bad debts of the improvident could be evaded by a refusal to attend except on a cash basis. Those unable to pay would, as at present, be cared for by the guardians, who would recover the costs later in the courts or from the rates.

If the Commissioners attempted to work the specially refractory areas this could be thwarted by a general refusal of the profession to work the other areas, not to mention financial aid to those locally hard hit. But the whole scheme is so much more than the mere provision of ordinary medical attendance, so interwoven with hospital treatment, for example, that the Commissioners, however tempted, would not be likely to force a deadlock. It is much more probable that they would report to the Government their inability to satisfy the profession.

If the Council really considers that the Commissioners can offer acceptable terms, why not wait until they are offered? Most of us consider they cannot, and will stand by our pledges.—I am, Sir, yours faithfully,

A HULL PRACTITIONER AND CLUB SURGEON.

Feb. 5th, 1912.

OXFORD OPHTHALMOLOGICAL CONGRESS.—This Congress will assemble at Keble College, Oxford, on Wednesday, July 17th next, and the meeting will be held on Thursday and Friday, July 18th and 19th. Members are reminded that cases and specimens will be welcomed. Mr. Sydney Stephenson, honorary secretary to the Congress, should be notified at 33, Welbeck-street, London, W., by any member willing to give any exhibition or demonstrate any operation. It is hoped that an "opaque projector" will be at the disposal of members for purposes of demonstration.

THE WAR AGAINST TUBERCULOSIS IN THE UNITED STATES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

The War Budget.

THE National Association for the Study and Prevention of Tuberculosis in the United States is justly proud of the work it has accomplished. The third annual statement of the expenditure incurred has just been published and deals with the year 1911. The total outlay for the erection of new hospitals and sanatoriums as well as for the treatment of patients slightly exceeded the sum of £2,360,000. The examination and treatment of patients at dispensaries account for only £170,000. The work of propaganda carried out by numerous local associations and committees cost £100,000, and £260,000 were spent in discovering and treating cases in schools, prisons, asylums, and for the cost of special work against tuberculosis undertaken by the public sanitary authorities. Some other small details bring up the grand total for the year's outlay to £2,900,000. This expenditure, while not much larger than that of the previous year, is equal to nearly double what was spent in 1909. It must be borne in mind that a sensational agitation has been organised in the States. This has its merits and its accompanying defects. Anti-tuberculous travelling exhibitions were sent round the country and lecturers accompanied these shows. Thus a number of persons were attracted who otherwise would not have given the subject a thought. A great mass of people, ignorant of medical questions, were familiarised with some of the leading principles of ventilation, cleanliness, the danger of sputum, and other simple rules of health for the prevention of tuberculosis. At the same time, among those who were thus taught there were here and there a few persons who had at once the kindliness of heart and the financial means to give monetary assistance to the movement. But it is necessary to bear in mind that this is a new movement, a new revelation to the great mass of the population showing what could and should be done. Under the spur of surprise and the charm of novelty generous enthusiasm was evoked, organisers and lecturers gave their services gratuitously, and voluntary subscriptions poured in from all quarters.

State and Municipal Help.

Wisely it has been foreseen that this enthusiasm could not be expected to last. The novelty would wear out, the enthusiasts would tire of giving voluntary service, other agitations would arise, and other calls would be made on the purses of generous subscribers. A well-organised sensation is very fruitful but short-lived. Once the mass of people are familiarised with the benefits of open-air treatment and with the fact that tuberculosis can to a large extent be prevented, they will attend other lectures, go to other museums, and subscribe money to some more novel form of agitation. Therefore to secure permanent benefit, the movement, while it lasts, must be directed upon the central and local authorities. Pressure must be brought to bear to compel them to establish permanent institutions that will continue to exist when the attention of the public is diverted in some other direction. Thus it comes about that to-day the National Association for the Study and Prevention of Tuberculosis is better pleased by the increase in grants which the State legislatures and the local or municipal authorities have made than by the increase of voluntary subscriptions. Also it must be borne in mind that the prevention of tuberculosis is a matter that concerns individually every inhabitant. The cost of prevention should, therefore, not be left to a few public-spirited and generous individuals, but form part of the local and national burdens. Consequently, the National Association is particularly careful to point out that the percentage of money contributed by the public authorities is greater in 1911 than before. It then amounted to 66·2 per cent. of the total, while in 1910 the money spent from the public funds was 62·6, and in 1909 only 52·5 per cent. of the total. For the present year large grants or subsidies out of the public funds have already been voted, and this money will be employed in dealing with tuberculosis. Of these sums, £940,000 are "from State appropriations" and about £1,140,000 for county or local purposes. The Federal Government, over and above this State and local expenditure, devotes about £200,000 a year to maintain several special sanatoriums for treatment of tuberculosis.

The States that have Done Best.

Of course there is a very great difference in the attitude of the various State legislatures, just as in England we find the county councils widely differ from each other in enlightenment and enterprise. In expenditure for the prevention of tuberculosis the New York State comes first, having spent last year for this purpose £710,000. Of this sum £211,000 were derived from voluntary subscriptions and the rest came from the public funds—that is, from the tax-payer. Pennsylvania comes next with an anti-tuberculous budget of £451,000, of which £109,000 were due to voluntary gifts. In Massachusetts the outlay for last year—and all the following figures are for 1911—was £221,600, of which £58,800 were voluntarily subscribed. The fourth on the list is Colorado, but here the situation is entirely reversed. Denver is the capital of Colorado, and its delightful climate has attracted many phthisical patients. Nevertheless, the public authorities have done little or nothing for these sufferers. Certainly there is the excuse that it is a new city and a new State. In 1880 there were only 35,630 inhabitants at Denver. Ten years later this number had increased to 133,859, and by that time the inhabitants were able to afford £500,000 to build their State house, but after a further 11 years of increasing prosperity they could not be persuaded to spend more than £13,100 for the war against tuberculosis. On the other hand the voluntary subscriptions exceeded that of all the other States except the State of New York, for it amounted to £136,000. The contrast given by the next on the list is in precisely the opposite direction; the proportion of voluntary subscriptions is lower in Ohio than in any of the other leading States; it amounts to only £15,000 out of a total of £144,400. In Connecticut the total is £119,400, the voluntary share of this being £25,900. In New Mexico, again a new State, the voluntary share is very high, £69,100 out of £118,100. Illinois, which is becoming an old State—in any case it is middle West and not far West—has barely a quarter of its tuberculosis budget from private subscriptions—namely £20,719 out of £94,885. Finally, Maryland, one of the oldest States, is indebted to private subscriptions for only £14,800 out of £78,000.

Municipalities and Dispensaries for Tuberculosis.

Such is the list of honour showing the total amounts spent by the nine States which are in the forefront of the war against tuberculosis. The older the State, the more experienced in legislative work, the greater the proportion of the expenditure borne by the public purse. In the raw new States there is less organisation, and much more depends on the initiative and enterprise of private individuals. In the older States the law is more likely to insist that the whole community shall pay for public services, and that such services shall be organised. Thus last year the State of Massachusetts enacted a law that every town with a population of 10,000 or more must establish and maintain a dispensary for the discovery and treatment of poor people suffering from tuberculosis. The towns are to be fined each time they are called upon to establish such dispensaries and fail to do so. Those towns that also establish a special hospital for the treatment of tuberculosis can obtain from the Commonwealth £1 per week for every patient they treat, who cannot pay for himself.

In Chicago there is the same tendency. Up to September, 1910, there were seven private dispensaries served by 25 physicians and employing 10 trained nurses, and they discovered and assisted a large number of cases. Now, however, the municipality has taken over these dispensaries, and are building a municipal sanatorium for the reception of 350 curable cases. The dispensaries will discover suitable cases for sanatorium treatment and will control the patients after their discharge from the sanatorium. Two new dispensaries and two new night clinics have been opened and the nursing staff doubled. The number of patients seen at the dispensaries was 20,139 in 1910 and 25,263 in 1911. The visits made to the homes of the patients increased from 18,500 to 27,174 in the last two years. 35 per cent. of the patients examined at the dispensaries were found to be tuberculous. In all, 7697 cases of tuberculosis were reported to the Chicago Health Department in 1911 and 5149 in 1910. Out of the total 12,846 cases of tuberculosis notified during the last two

years 20 per cent. were reported by the tuberculosis dispensaries.

The Campaign in Pennsylvania.

One of the leading authorities on the question in the United States, Dr. Lawrence F. Flick, has recently issued a report on the progress of the campaign in Pennsylvania, which, it appears, began in 1892 by the formation of a Society for the Prevention of Tuberculosis. Before that time the harbouring of patients in the general hospitals and almshouses had helped to isolate advanced cases and thus prevent the spread of the disease. Dr. William Webb, however, taught that tuberculosis was contagious early in the "eighties," and Koch discovered the tubercle bacillus in 1882. As these new doctrines spread, doubts arose as to whether tuberculous patients should be admitted in general hospitals and almshouses, and in the course of time many special institutions were created. There are now in the State 14 charitable institutions with 600 beds, two public institutions with 1100 beds, and six run for profit with 100 beds. Then there are 125 dispensaries, and most of them give free milk and eggs to poor patients. Since the commencement of the campaign and up to 1911 Dr. Flick estimates that about £1,200,000 have been spent in Pennsylvania in the crusade against tuberculosis. Of this the amount contributed by private societies was a little over £400,000. The Commonwealth of Pennsylvania spent £600,000 and the city of Philadelphia £200,000; nearly two-thirds of the entire amount has been spent since 1907, and there are now about 1800 beds available for tuberculous cases.

Effect of Tuberculosis on the General Death-rate.

The statistics show, for instance, that whereas in 1870 at Philadelphia 3·42 and in Pennsylvania 2·13 per 1000 of the population died from tuberculosis of the lungs, these figures were reduced to 1·85 and 1·15 per 1000 respectively in 1910. Dr. Flick, however, insists that what with the change of views as to tuberculosis and the acceptance of the theory of contagion, there have been some suppression and change of nomenclature as to the cause of death, which must slightly affect the accuracy or comparative value of the statistics. Indeed, the word tuberculosis was not officially introduced in the nomenclature of the State before 1904, though it had been used unofficially some time previously. Then, again, many patients went away to a better climate who would now have spared themselves this trouble. The reduction in the death-rate from this disease has been greater in the towns than in the rural districts. Outside of Philadelphia and throughout the State the reduction since 1870 is estimated approximately at 48 per cent.

For the city of Philadelphia Dr. Flick has drawn up three tables. The first table contains the deaths which by common consent are undoubtedly due to tuberculosis. The third table contains deaths attributed to a great variety of diseases which are sufficiently similar to tuberculosis as to serve as a cloak to conceal the truth. Then there is an intermediary or second table where many names are also used, but which can with less hesitation be earmarked as tuberculosis. These three tables are so comprehensive as to include every death that has occurred during the 40 years which may be due to tuberculosis. The reduction in the "tuberculosis" table in the 40 years was equal to 41·6 per cent., and the "probably tuberculosis" 89 per cent., the mean being 68·7 per cent. More than one half of the reduction has occurred within the last ten years, but there has been no corresponding reduction in the death-rate from other diseases. On the contrary, excluding the "tuberculosis" and "probably tuberculosis" the death-rate was 14·31 per 1000 in 1870, 13·93 in 1880, 14·82 in 1890, 14·80 in 1900, and 13·50 per 1000 in 1910. By also excluding the "possibly tuberculosis" the death-rates during the same five years mentioned above are 8·04, 8·18, 8·11, 9·0, and 8·42 per 1000.

Isolation and Sanitation.

From his observations Dr. Flick concludes that the reduction in the death-rate largely depends on the isolation of "open, ulcerative, pulmonary tuberculosis." He therefore argues that in the campaign against this disease much simpler means might be employed. Before the scare about the contagious character of tuberculosis the open ulcerative cases were accepted in the general hospitals, especially during the final, and for the public the most dangerous, stages. Dr. Flick insists that isolation is the most effective preventive, but that it is not necessary to have special hospitals for this purpose. "It has been found," he says, "that advanced cases can be treated in any hospital with entire safety to other inmates of the hospital provided certain simple rules of cleanliness are strictly lived up to." If the sputum is properly disposed of the moment it is given off the patient can be made "non-contagious and be safely kept in any locality." Also the general hospitals are usually nearer to the homes of the people, so that less objection is raised to the separation caused by isolation.

It is strange that in all this, and while recording the great reduction achieved in the prevalence of tuberculosis, Dr. Flick has not a word to say about the general sanitary improvement which assuredly must have been accomplished during the last 40 years. One of the great advantages of the campaign against tuberculosis is that it touches on so many other matters besides the one disease. Poverty, filth, overcrowding, bad drainage, the pollution of air, the adulteration of food, the contamination of water, and the consequent reduction of human vitality—these are the conditions that favour disease and that prevail where tuberculosis claims the largest number of victims. As sanitation has improved so has the frequency of tuberculosis declined, and the same may be said of many other diseases. At the same time everyone will recognise that the more overcrowded and insanitary a district the more necessary it is to remove cases of tuberculosis that are so far advanced as to become centres of contagion.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

Noisy Cars at Night.

THE Commissioner of Police for the metropolis has issued a most reasonable and courteous circular in which he points out the seriousness of needless use of sirens, open cut-outs, and multiple horns, especially at night time, and he appeals to all drivers to assist in diminishing this nuisance. The disturbance to all residents in London is undoubted, and it is certainly to be hoped that his appeal will have the desired effect.

The New Bosch Dual Ignition.

For the medical motorist it is an advantage to have a dual method of exploding the mixture of a petrol motor. To start off, possibly to a most urgent case, and to be delayed perhaps miles from a repair shop on account of ignition faults, is more than annoying. Of course, it can be argued that the modern magneto rarely gives trouble, and I quite admit it; but it may. In motoring, as well as in other affairs, the nnexpected occasionally takes place. It is thus as well to have, if possible, a dual ignition, and a very good one has been put on the market by the Bosch Magneto Co., Limited, of Newman-street, London, W. The apparatus consists of either a vertical or horizontal coil, the winding of which is similar in design to the armature of the Bosch arc-light magneto, and the spark produced is in every way as effective. The switch and coil are combined in one, so that external connexions between them are entirely dispensed with. A compound cable consisting of four differently coloured and highly insulated conductors is supplied, and most of the Bosch magnetos can now be converted to this dual system at a moderate cost. The device is provided with a locking arrangement guarding against the improper use of the car. This is important, for many medical men on their rounds leave no one to guard their automobiles while they are inside a patient's house, and it is a satisfaction to know that the "young fry" cannot start the car in addition to blowing the horn.

An Electric Car Cleaner.

In these days of cloth upholstery it is rather difficult to keep the interior of a landaulette clean, and therefore the "suction" cleaner, which dislodges dust that an ordinary brush will not reach, is useful. A suction cleaner, which is known as the "Nuway," is sold by the London Motor Garage Co., of Wardour-street, London, W., which is easily

attached to any electric light holder, and is, I understand, not extravagant.

Cost of Motor v. Brougham.

We have referred above to the experience of "F.R.C.S. Eng.," who now sends us the following additional details:—"*Cost of running a 15·9 h.p. Daimler limousine motor-car in 1911:*—

Total mileage	5650 miles.
For pleasure, about	1300 ,,
For professional purposes, about	4350 ,,
Total cost for year (including depreciation)	£306 9s. 7d.
Chauffeur	90 14s. 0d.
All other costs	110 0s 0d.
Depreciation 20 per cent. of £523 18s. 2d. (initial cost)	105 15s. 7d.
Total cost per mile, nearly	1s. 1d.
Chauffeur, per mile nearly	3·9d.
All other costs per mile	4·6d.
Depreciation per mile	4·5d.
Petrol used, approximately	280 gallons.
Miles per gallon, approximately	20 miles.
Car unavailable on account of re-varnishing and repairs	21 days.

The car was bought in June, 1910.

The *former cost of brougham and two horses* (one in morning, the other in afternoon) was:—

Total cost, including depreciation	£210 0s. 0d.
Mileage (all for professional purposes) about	4000 miles.
Cost per mile	1s. 0½d.

The limousine exceeds the brougham in appearance, readiness, speed, comfort, convenience, and exhilarates the mind, whilst driving in a brougham dulls it. I should not like to go back to the latter. Thanks to the chauffeur, the car looks almost like a new one."

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis Exhibition.

AT a meeting of persons interested in the campaign against tuberculosis, presided over by the Lord Mayor, it has been decided to hold an exhibition in June to demonstrate to the poorer classes how tuberculosis may be prevented. A large and influential general committee has been formed, containing representatives of the medical profession, the health committee, boards of guardians, city aid society, and the other agencies interested in the public health, with the Lord Mayor as president, to make the necessary arrangements for the success of the exhibition.

General Hospital.

The vacancy created by the resignation of Professor Robert Saundby as physician to the General Hospital has been filled by the election of Dr. J. W. Russell, the senior assistant physician. Dr. Russell has had a very long period of service in the out-patient department, and his appointment to the post of full physician will be a very popular one. He recently met with a severe accident, the motor-car in which he was riding colliding with a tramcar during a dense fog, but is now making good progress towards complete recovery.

Feb. 6th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Royal Infirmary.

AT the annual meeting of the Royal Infirmary held on Feb. 5th a highly satisfactory report of the year's work was presented. The fact was deplored that there was a debt of upwards of £8000 hanging over the institution, and an appeal was made for increased public support. Mr. Ralph Brocklebank was elected president for the ensuing year. Mr. Brocklebank is one of those public men who support the charities of the city, not only with their substance, but also with their personal services. He has been a member of the committee of the "Royal" for upwards of 35 years. For 30 years he discharged the onerous duties of honorary treasurer, and for five years he has been chairman of the committee. His practical knowledge of both the policy and administrative details of the infirmary is very extensive. It may be safely asserted that no Liverpool citizen is worthier of the honour conferred upon him by the trustees of the hospital. The Liverpool School of Tropical Medicine attached to the University of Liverpool, having felt that their important work could be carried on in a more satisfactory way if they had ward accommodation near to the University to enable the students to watch the constant changes in patients suffering from those diseases, approached the committee to see if such accommodation could be provided. Negotiations were now in progress, and it was hoped that they would result in the making of satisfactory arrangements. The value of the new out-patient department was amply demonstrated at the time of the great strike riot on Sunday, August 13th, when some 200 cases were brought to the hospital for treatment in about two hours. The sudden rush of so many surgical cases depleted the stock of dressings, &c., thereby putting the hospital to very considerable expense in replacing those articles. During the year electric lighting had been extended throughout the hospital and residential blocks, and the three lifts were also being electrified with a view to economy in working.

Liverpool Infirmary for Children.

At the annual meeting of this charity, held on Jan. 30th under the presidency of the Earl of Derby (Lord Mayor of Liverpool), the report showed that the number of patients treated during the year were: in-patients, 1338; out-patients (new cases), 15,590; attendances, comprising old and new cases, 55,308. Lord Derby, in noting that cognisance was taken in the report of the question as to whether the Insurance Act when it came into actual operation would affect adversely the finances of the hospital, said that he had not the slightest doubt that it would mean the withdrawal of a certain number of subscriptions; possibly not quite so many as people thought, but there was certain to be a reduction. He did not want to enter into political matters, but the question was whether when the Act came to be amended, as amended it must be, as nearly every Act was, by having the rough corners knocked off it, it would not be found that some contributions paid under it would find their way from the State through the individual to the hospitals. He should vehemently oppose the State or the municipality having anything to do with the management of voluntary hospitals because, in the first place, it would kill voluntary effort, which was the essence of the good work of those institutions; and, secondly, from what he knew of Government departments it would certainly mean increased expense.

The Lancashire County Council and the Danger of Vaccination Exemptions.

At the quarterly meeting of the Lancashire county council held on Feb. 1st, on the motion of Mr. Robert Sephton, the chairman of the public health committee, it was resolved to support the Cumberland county council in drawing the attention of the Local Government Board to the grave menace to public health disclosed by the large increase of exemptions obtained from vaccinations since the year 1903, the increase in the administrative county being about 600 per cent., or from 3 per cent. to 21 per cent. of the births.

Runcorn Sanitation.

Mr. Tulloch, Local Government Board inspector, held an inquiry last week into the application of the Runcorn urban council to borrow £8000 for sanitary works in the town and £2000 for water-main extensions. Considerable opposition was forthcoming to the first part of the application from property owners. The authority proposed to serve notices on the owners of a large number of houses, compelling them to convert the existing ashpit privies to the water-carriage system. If the notices were not complied with the council would do the work and bear half the cost. There were 2600 ashpits in the town. The property owners urged that the cost of the conversions was excessive. The inspector said that property owners who did the work themselves and paid the whole cost need not confine themselves absolutely to the specifications, but were bound to do the work to the satisfaction of the council. There was no opposition to the application for a loan for water purposes.

Feb. 6th.

NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The Insurance Act: A Local Member's Views on the Profession.

DURING January Mr. J. M. Robertson, M.P., Parliamentary Secretary to the Board of Trade, held several meetings in his constituency, the Tyneside Division. His first meeting was held on Jan. 15th, and dealing with the opposition to the Insurance Act he remarked "that the measure was perhaps a little ahead of public opinion. They could not change society without pinches and wrenches somewhere. The healing profession had shown more readiness to cry before it was hurt than any other section of the community. It was an unfortunate fact that the bulk of the profession were Tories, the reason being that they had to give so much time to the laborious training needed for their own profession that they knew very little about anything else—he meant in a public way. They were the worst set of politicians in the country and never seemed to find time to make themselves good politicians. The majority of them were probably Tariff Reformers, and it was on that ground, he was afraid, that they had been so ready to set up all that violent and furious opposition to the Insurance Act. If it had been a proposal to levy a tax to make the people's food and boots dearer there would have been no meeting of doctors to protest. They would have said nothing."

This quotation is from the local press, and the effect of this account of the meeting was what might have been expected. Members of the medical profession wrote to the press controverting the various statements, one of the most prominent of such letter-writers being Dr. Mears, of North Shields, who dealt with the points of Mr. Robertson seriatim, and denied the statement that most doctors were Tories and Tariff Reformers,

A day or two later at another meeting, Dr. T. L. Bunting being in the chair, Mr. Robertson said: "He thought that medical men had been strangely ready to cry before they were hurt. If here and there the position of the doctors was found to be a little worse measures would promptly be taken to remedy the evil. His own belief was that the income of the profession would be considerably added to." At the end of Mr. Robertson's address Dr. Bunting observed he was sorry that Mr. Robertson had made an attack on the profession, adding, "Honestly, I do not think he understands it." The chairman went on to point out that if the way of living of any other section of the community, say the miners, had been altered by a Bill without any previous consultation there would have been a great ferment. He did not think the attitude of the profession was dictated by their politics, except in the case of a few extremists. He was quite sure that a number of doctors were going to suffer heavily, and he wished to protest against what he thought was to some extent an attack on the honour of the profession to which he belonged. Mr. Robertson, replying to this criticism, considered that it was the generosity of the chairman which made him take a chivalrous stand. He repeated that those who were concerned about the Act did not believe that the doctors would suffer, and that if here and there under special circumstances the doctors were worse off, remedies would be applied.

Further letters have appeared in the press concerning Mr. Robertson's views, and in one of his speeches Mr. Robertson described the medical criticisms as "childish," based on Tory feeling against a Liberal measure, and that he did not propose to deal with them in the press but to leave himself to the judgment of his constituents.

The net result of the remarks of the honourable member has been to create a feeling among the profession that no medical man should in the future support Mr. Robertson by taking the chair at his meetings. Mr. Robertson has had three medical chairmen, which ought to have proved to him that medical opposition to the measure is not founded upon party politics.

Proposed Tuberculosis Dispensary in Newcastle.

A conference of representatives from the city sanitary authority, the board of guardians, the Royal Victoria Infirmary, the Dispensary, the Hospital for Sick Children, the Northern Counties Hospital for Consumption and Diseases of the Chest, and the Northumberland and Stannington Sanatoria, was held on Jan. 19th in the council chamber at the Town-hall, Newcastle-on-Tyne. Sir Henry Newton presided. A statement was submitted from the medical officer of health, containing an estimate for the requirements of a tuberculosis dispensary to be established in the centre of the town. The cost was estimated at £1500 per annum. Sir George Hare Philipson proposed, and Dr. T. Beattie seconded, the adoption of the draft scheme, with the substitution of three advisory medical officers at £50 per annum each for the proposed two officers of the scheme. An amendment was moved by Dr. T. M. Allison, seconded by Dr. A. T. Wear, that instead of three advisory officers there should be six honorary officers. The amendment was lost and the original motion carried by a large majority. The further procedure in this business will be the submission of the scheme to the sanitary committee and then to the city council for confirmation. No doubt should the matter be confirmed there will be more details of the scheme set forth than have been given to the public up to the present.

The Scourge of Phthisis: Workmen and the Barrasford Sanatorium.

A meeting has recently been held between representatives of the committee of the Newcastle and Northumberland Sanatorium (Barrasford) and the representatives of the Medical Charities Fund of the various works on Mid-Tyne, for the purpose of the provision of maintenance of patients from the Mid-Tyne district requiring sanatorium treatment. Up to the present the sanatorium has not been one of the charities benefiting under the Medical Charities Fund, and the object of the meeting was to awaken interest in the efforts made at Barrasford to combat the disease of tuberculosis. Sir George Hare Philipson occupied the chair, and there were representatives from the great works on Tyneside. Councillor Smith (of the Newcastle corporation), in the course of his remarks, explained that to some extent the Newcastle corporation had led the way locally in the campaign against the disease by taking 20 beds in the sanatorium at a total cost of about £2000 per annum. After the discussion which followed it was considered that the best way to raise money for this particular purpose was that of a small levy among the workmen, and the meeting concluded with a discussion as to ways and means.

Feb. 6th.

WALES.

(FROM OUR OWN CORRESPONDENTS.)

The Welsh National Memorial.

THE promoters of the Welsh National Memorial to King Edward VII. set themselves the task of obtaining the sum of £300,000, and proposed to capitalise that amount and use the income in carrying out measures having for their object the prevention of, and they hoped the extermination of, tuberculosis within the Principality. The fund now amounts to nearly £200,000, and £178,000 have been invested. The introduction of the National Insurance Bill, including as it did provision for the treatment of tuberculosis, had the effect of diminishing very largely the number and amount of public subscriptions, but now that Insurance Commissioners for Wales have been appointed, and the distribution of grants for sanatoriums and other institutions will be largely in their hands, it is anticipated that further subscriptions to the Memorial Fund will be forthcoming, especially as it is understood that grants under the Insurance Act will be dependent upon the amount of local support obtained for sanatorium and other purposes. Active steps are being taken to incorporate the National Memorial Association by Royal charter. The work already carried on by the association includes an educational campaign by means of lectures, the distribution of literature, and by a travelling tuberculosis exhibition. Arrangements have been made to take over the West Wales Sanatorium at Alltymynydd in Carmarthenshire, which was opened in 1905, and the Penhesgyn Open-air Home in Anglesey. Twenty-five nurses are to be specially trained in tuberculosis work to act under the auspices of the association in different parts of the country.

The Classification of Paupers.

A further step has been taken by the Poor-law authorities in the three West Wales counties of Carmarthen, Cardigan,

and Pembroke in the direction of classifying on an extended scale the occupants of workhouses. At a conference of delegates from the various boards of guardians held at Carmarthen on Jan. 27th the Poor-law inspector of the Local Government Board, Mr. Hugh R. Williams, said that unless the guardians tackled the question of the feeble-minded it was probable that some other authority would be entrusted with it. In the 13 unions in the three counties there are 212 imbeciles and feeble-minded, 76 being in workhouses. The asylum authorities, in Mr. Williams's opinion, should deal with dangerous lunatics and the Poor-law authorities with the harmless and incurable, and of the two last-named there are a sufficient number in West Wales to justify the provision of a common home. He suggested that the Lampeter and the Tregaron workhouses might be used entirely for special purposes, the latter possibly for consumptives. With more general and complete classification he considered it would be possible to do away with half a dozen of the existing workhouses. The members of the conference passed a resolution to the effect that the time was ripe for the serious consideration of the condition of harmless lunatics and of the feeble-minded, and a committee was formed to draw up a scheme for more complete classification.

Infantile Mortality in Brynmawr.

In his annual report for 1911 the medical officer of health of Brynmawr, Mr. J. L. Thomas, states that the high death-rate among young children, which was equal to 145 per 1000 births, was due in great measure to the prevalence of diarrhœa during the summer months. Having in mind the important part played by improper feeding in this disease he adopted the novel method of distributing information as to the right method of feeding and rearing infants through the school children. But instead of giving them printed circulars to take home he caused appropriate instructions to be dictated to them. They then made a fair copy and took this to their homes, and it was hoped that this course would be more likely to impress both the children and the parents than if printed matter was distributed.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Royal Colleges and the Conference.

A MEETING of the Royal College of Surgeons of Edinburgh was held on Wednesday, Jan. 31st, to consider the invitation which had been received to attend a conference with the Insurance Commissioners. The meeting decided not to appoint representatives to attend the conference, but while declining the invitation, agreed that the Commissioners should be informed that some time ago intimation was made by the College to the Chancellor of the Exchequer that the medical provisions in the Insurance Bill were so unsatisfactory both to the interests of the public and the medical profession that, in its view, this part of the Bill should be withdrawn. To this opinion the College still adhered. The Royal College of Surgeons of Edinburgh was, however, willing to render any assistance in its power to the Commissioners should they determine to exercise their statutory powers in altering the terms contained in the Act, or to aid the Government in drafting an amending Bill, which would safeguard the health of the public and preserve the educational and professional interests of those whom the College represented.

A meeting, called for a similar purpose, was held by the Royal College of Physicians on Thursday, Feb. 1st, but some minutes before the hour of meeting a telegram was received from the secretary to the Commission intimating that the conference was "postponed." On the President taking the chair, he intimated the receiving of the telegram, and left it to the College to determine what their action should be under the circumstances. The College decided not to discuss the matter, but to pass from the special business for which the College had been called to meet. So, for the present at least, the question of a conference has ceased to trouble the mind of the profession in Scotland. How much opinion in Edinburgh may have been influenced by the strong lead given by the Royal College of Physicians of London, which met on Tuesday, Jan. 30th, it is impossible to estimate accurately, but the honour of priority lies with the London physicians, and they have the satisfaction of having had their action endorsed.

The Scottish Medical Insurance Council.

The Executive Committee which was appointed to take steps for the calling together of this body has issued to every practitioner in Scotland a copy of the statement. The statement indicates the steps by which combined action was arrived at and the constitution of the council which it is proposed to set up in Scotland. The council is to consist of one or more representatives from the insurance areas, as these are already defined in the Act; of the Scottish Committee of the British Medical Association; of representatives of the Universities; and of representatives of the Scottish medical corporations. This council when it meets will have to determine what policy is to be followed, and will select an executive to carry out its policy. The practitioners in the areas are requested to nominate suitable men from their respective areas, and to facilitate this being done each practitioner has been supplied with a nomination form; each person nominated must have both a proposer and seconder. The nomination papers have to be sent in to the secretary of the British Medical Association division in which the area is situated, and to facilitate this being done by those who are not members of the British Medical Association there is a list of the insurance areas showing the division in which each area is placed and giving the name and address of the divisional secretary. Every endeavour has thus been made to make the arrangements as simple as possible. After the nominations have been received voting papers will be sent out.

Measles at Inverallochy.

The public school at Inverallochy has been closed on account of an epidemic of measles. Over 30 per cent. of the pupils were absent, principally from the younger classes, the infant department being practically without pupils.

Contaminated Water at East Wemyss.

At a meeting of the Kirkcaldy district committee held on Jan. 27th, Dr. A. L. Currie, medical officer, reported on three deaths which took place at East Wemyss some time previously. The deaths took place after a dance, at which seven people had drunk water from a burn running through the village, which had been brought in for the purpose of washing dishes. Three of the seven had died, and Dr. Currie believed that their deaths were caused by the contaminated water they had drunk. There was a water famine in the district at the time. It was ultimately remitted to the clerk to consider who was responsible for the cleaning of the burn.

Honour to Dr. W. Simpson, of Buckie.

In presence of a large and representative gathering in the Masonic Hall, Buckie, on Feb. 2nd, Dr. W. Simpson was presented with a pony and trap and a silver salver in recognition of 40 years' service in the district. Ex-Provost Webster made the presentation, and in doing so said that it had arisen from a spontaneous desire on the part of Dr. Simpson's many friends to mark in some way their respect and esteem for him and their appreciation of his long period of service, over 40 years, in the community. Forty years was a long period in the life of any man, and in Dr. Simpson's case it represented 40 years of the best part of his life spent in their midst. Dr. Simpson's reply was an eloquent *résumé* of 40 years of country practice.

Dr. Thomas Wright, of Wick, has been appointed one of the medical referees under the Workmen's Compensation Act, 1906, for the sheriffdom of Caithness, Orkney, and Shetland.

The death occurred on Jan. 21st, at Tannadice, of Dr. David Kydd, at one time a well-known medical practitioner in Forfarshire.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Act.

THE Conjoint Committee of the British and Irish Medical Associations has issued a circular to members of the profession calling attention to the position of Ireland under the Act. It is remarked that under the Act, which comes into force on July 15th, no work will be required of the profession until January, 1913, and then only certificates. The question of remuneration for these will require careful consideration.

The compulsory section which was in the original Bill is *not* in the Act. Owing to the elimination of "medical benefit" there is outside the Act a great danger of a widespread and immediate introduction of contract practice absolutely under the control of Friendly Societies with enormously augmented membership. Later on approved societies with sufficient funds may introduce "medical benefit" as an "additional benefit." This may be administered under the same conditions as "medical benefit" in Great Britain, but the Irish Commissioners have power to leave the administration in the hands of the Friendly Societies, which, of course, would be directly opposed to the interests of the profession. For the present no arrangements of any sort should be made with Friendly Societies without first communicating with this committee. Further, the profession in Ireland has no voice in the selection of the medical men who are to serve on the Insurance Committees, as is conceded in Great Britain.

The Irish sense of humour has been tickled by the appearance in the Irish papers of advertisements by the Insurance Commissioners for applications from friendly societies, trade unions, public bodies, or other bodies desiring to become approved societies under the Act for the service of lecturers on the Act. It is proposed to form classes in Dublin and Belfast and other large centres where officials of existing organisations may receive special instruction. The Parliamentary Committee of the Irish Trades Congress has passed a resolution requiring the extension to Ireland of medical benefits under the Insurance Act. Mr. John Dillon, M.P., defending the Nationalist Members of Parliament for not allowing medical benefits to extend to Ireland in a letter published on Jan. 31st, says the Old Age Pensions and the Insurance Act have laid the basis for the abolition of the Poor-law system in Ireland; and that, in all probability, the decision of the Irish people will be to apply medical benefit in conjunction with a reform of the dispensary system.

The Women's National Health Association and the Insurance Act.

The proposed Irish Health Society under the Insurance Act was brought before a special meeting of the Enniskillen branch of the Women's National Health Association on Jan. 31st, Mrs. E. M. Archdale presiding. After Mr. Alexander Irwin, LL.D., of Coleraine, who had been specially sent, had explained fully the working of the Act, the lady who presided said she would not like to advise anyone to join this proposed Irish Health Society without being able to tell them its advantages over other societies. With one dissentient the committee decided not to undertake as a branch the working up of the Irish Health Society.

Esperanto and Medical Study.

At a meeting of the Dublin University Biological Association last week Mr. G. Jameson Johnston gave an address on the Use of Esperanto in Medical Study. He pointed out that it was not intended as a universal language but merely an auxiliary language. The Provost of Trinity College, who was present, joined in recommending the study to medical students. The next British Esperanto Congress is to be held at Portrush at Whitsuntide.

Association of Fellows of the Royal College of Surgeons.

The annual dinner of the Association of Fellows of the Royal College of Surgeons was held last week at the Dolphin Hotel, Dublin, under the presidency of Lieutenant-Colonel F. G. Adye-Curran, R.A.M.C. (retired). The principal speaker was Mr. Frederick Spicer, of London. Discussing the reasons why more Fellows of the College did not join their association, he said it was due to either ignorance or inability to appreciate the objects for which they had been working. There might be some exception taken to their original founders, and it seemed to be feared that they were a discontented lot of revolutionists, ready to pull down everything in order to get something out of the ruins. On the contrary, they claimed to be equal members of an ancient and honourable College, of whose name they were justly proud and jealous. They were banded to aid and assist the College in every way and to promote her interests. But financially the state of affairs was rotten. Professors were underpaid, and work was starved for want of money. Fellows of the Royal College of Surgeons in Ireland, however eminent they might be, were insulted and flouted in England, and were not eligible for, and were shut out from, surgical appointments in that country, which were kept for a little clique of the Royal College of Surgeons of England. Certain English hospitals made it a condition of appointment that the applicant be a Fellow of the Royal College of Surgeons of England, which debarred the Irish and Scotch diplomates. The Association of Fellows of the Royal College of Surgeons in Ireland protested against such invidious distinctions, and pointed to the fact that some of the most eminent surgeons in England at present were Fellows of the Irish College. The chairman called attention to the National Insurance Act, and expressed the hope that the Government might see its way to introduce during the coming session some sort of an amending Bill which would render it more acceptable to the profession at large. Speeches were also made by Professor J. A. Scott, Mr. Andrew Smith, J.P., Mr. John O'C. Delahoyde, Mr. Andrew Charles, and Mr. Shepherd Boyd.

Health of Belfast.

The report presented to the city council of Belfast on Feb. 1st, regarding the health of that city between Dec. 17th, 1911, and Jan. 13th, 1912, showed that the death-rate from all causes had risen to 17·9, while the zymotic rate was 1·2 and the mortality from chest affections was 5·2. The notifications of all infectious diseases except erysipelas, of which 20 cases were notified, had diminished. There is a marked decrease in the reported cases of scarlet fever and diphtheria. Two cases of typhus fever were also notified.

Infantile Paralysis to be a Notifiable Disease.

At a meeting of the city corporation of Belfast on Feb. 1st it was decided to add infantile paralysis to the list of notifiable diseases.

Forster Green Hospital for Consumption.

At the sixteenth annual meeting of this hospital, held in Belfast on Jan. 31st, the medical report showed that at the beginning of the year there were 49 patients in the hospital, and that 297 were admitted, thus making a total of 346 treated during the year. On an average the patients remained between 10 and 11 weeks in hospital, a period shorter than in former years, chiefly owing to the fact that the corporation patients are admitted for only three months, at the expiration of which they are discharged. The idea of the health committee of Belfast in making the time of residence in hospital so short is to give the benefit of sanatorium treatment to a larger number of consumptives, but in the case of hopeful patients making good progress the time is much too short to ensure a permanent arrest of the disease, and in many such cases the physicians of the Forster Green Hospital report that they have witnessed a relapse of the disease after discharge in cases which might have been permanently cured. During the 12 months the amount received in subscriptions had fallen off, while owing to the increased price of provisions ordinary expenditure had increased, as well as special expenditure in repairing the buildings.

Feb. 6th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

The Squatters Bill.

IN connexion with the labour shortage both mine-owners and farmers have been agitating for legislation that will increase the present labour supply in South Africa, and the result of the agitation is now seen in a Government Bill published a few days ago—the Squatters (Native) Bill. At the present time there are many thousands of native families occupying portions of farms and earning a living by tilling the soil and paying rent to the owners. It is true that in many cases exacting landlords demand a rental which renders it well-nigh impossible for the native tenants to subsist, and that a number of other abuses have crept in, but still there is no justification whatever for some of the proposals in the measure, and particularly for the main principle which appears to aim at driving native tenants off the lands into native locations with the object apparently of forcing them to work in the mines or on the farms. In the former case they have to work under the unhealthy conditions of labour prevailing in the gold mines, or in the latter for farmers—who include some of the greatest sweaters of labour in South

Africa. This Bill may drive into pauperisation and misery many thousands of natives, yet it will probably be passed.

White Nurses for Natives.

At a meeting of the board of the Kimberley Hospital the other day the Mayor of Beaconsfield moved a resolution protesting against the employment of European female nurses in wards where male natives are under treatment. Dr. J. E. Mackenzie offered a spirited opposition to the proposal, and made it clear that there was no proof whatever that what is called "the Black Peril" is affected in any way by the professional contact of white nurses with coloured men. He showed, indeed, that the record of this class of crime is all against the idea. The proposal did not find a seconder, and the discussion, owing to Dr. Mackenzie's attitude, quickly fizzled out. Unfortunately, the lay press seems inclined to take the matter up.

Rabies in Rhodesia.

At the present time there is occurring what threatens to be one of the most serious outbreaks of rabies in Rhodesia which the Government of that country has had to face. Since the epidemic some years ago, when the whole country was practically swept by the disease, a few cases have appeared here and there, but confined for the most part to the Victoria district. Now, however, the disease appears to be spreading throughout the adjoining districts. Quite a considerable number of persons have had to be sent to the Government bacteriologist at Salisbury to undergo inoculation after being bitten by dogs which have been proved, or are believed, to have been rabid. The Government Veterinary Department now adopts the plan, upon an outbreak of rabies, of compelling owners of dogs in an infected district to tie their animals up, and the police and private citizens are empowered to shoot on sight any dog found at large. Despite this step, however, the disease appears to be spreading, and if it is to be stamped out more stringent steps will have to be taken.

Whaling on the South African Coast.

During the past two years it has apparently been realised that there is a rich living to be made in connexion with whaling operations on the coast of South Africa, for a number of whaling stations have been established, and numerous applications for fresh sites on which to establish new stations have been made to the Government. Unfortunately, the existing stations have been under no sort of supervision, and most of the structures that have been erected are wooden ones. The process apparently consists in boiling down by steam the whale blubber, bones, and meat. The stations have become saturated with oil and grease and emit a stench that is apparent for miles around. As a result local authorities have opposed most of the recent applications for sites and industrial enterprise is driven away. If it were recognised that a factory, built of reinforced concrete and with a modern automatic plant, could be worked even in the warm climate of South Africa without becoming a nuisance, it is probable that those who are responsible for the antiwhaling movement along the coast would change their attitude and welcome the establishment of the same. It is understood that a modern factory is to be established at Luderitzbucht, in German South-West Africa, and perhaps this will provide the necessary object-lesson.

Death of Mr. H. C. Keilly-Flynn.

Mr. H. C. Keilly-Flynn passed away in Pretoria a few days ago after a short illness. He was generally believed to be a medical man, but as a matter of fact was unqualified, though he had studied medicine in Dublin in 1838. He appears to have been originally appointed surgeon, in the free and easy method prevalent at the time, to the 17th Lancers, and came out to South Africa in that capacity, and on the return of his regiment he relinquished his commission and remained in the country. In 1877 he was in practice in Rustenburg, and hoisted the first Union Jack which proclaimed the annexation of the Transvaal in 1877. In 1881 Mr. Flynn brought this flag into Pretoria, and on August 2nd buried it in the presence of the garrison after a coroner's verdict had been returned of "Death due to a wrong diagnosis of Boer character and general bungling of one man at home." A wooden tablet with an inscription ending with the word "Resurgam" was placed over the grave. When the British troops entered Pretoria on Sept. 25th, 1900, the deceased was elected by the English inhabitants to present an address to Lord Roberts, and the flag was dug up and presented to the colonel of the 21st Lancers. Deceased had at one time many patients, but he was better known for his literary attainments. He was a patriot in the true sense of the term, and suffered for his patriotism. The news of his death has been received with genuine regret by a host of friends and by many erstwhile enemies, who have come to realise the sterling worth of his somewhat rugged character.

A Sanatorium for Miners' Phthisis.

The sanatorium for miners suffering from miners' phthisis, which has been erected at a cost of £52,000 at Modderfontein, was opened recently by the Administrator of the Transvaal. The sanatorium is a two-storeyed building, built in the shape of a crescent, facing north. There are four six-bedded wards on each floor and a number of smaller wards. The buildings are admirably suited for the purpose for which they are intended to be used, but it should have been possible for more accommodation to be provided for the money. The medical superintendent is Dr. J. C. Mitchell, late Government bacteriologist and pathologist of the Transvaal.

South African Medical Congress, 1912.

The preliminary arrangements have been completed for the next South African Medical Congress, which is to be held in Johannesburg during Easter week next. An entertainment committee is busily engaged in arranging a programme of entertainments, but it is sincerely to be hoped that festivities will not be permitted, as is so often the case at these gatherings, to interfere with the real business of the Congress.

Dec. 27th, 1911.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Sanitary Administration in Bengal.

FROM the report of the Sanitary Commissioner for the Province of Bengal we learn that in 1910 the birth-rate was 39·72 per 1000, an increase of 1·93 over the rate for the previous year, due to an improvement in the health of the population and a greater abundance of food-supply. The death-rate, however, was also higher, 33·10 compared with 30·55 per 1000, owing to the prevalence of cholera and plague. These ratios are based on the figures of the 1901 Census—viz., 50,521,604. According to the 1911 Census the population amounted to 52,457,011, but the figures are not yet available for statistical calculations.

Among the populations of India there is a natural increase in their numbers with favouring conditions of the food-supply and of health, which under the peaceful Government of the British *raj* would soon produce a state of overcrowding were it not for occasional epidemic visitations. Bengal, however, has by no means the most prolific population, as in the Central Provinces the birth-rate was as high as 55·42 per 1000, the highest recorded during the last 30 years, and the result of a healthy and prosperous season in 1909. In the United Kingdom the years are nowadays always healthy and prosperous in regard to essentials, yet the birth-rate has fallen to 25 per 1000 in 1910. The statistical figures indicate the point of view of the people; the poorest Bengali considers it a disgrace not to have a family, and has no anxiety as to its maintenance after the period of childhood, a matter which he entrusts to Providence and the Government.

The higher mortality in Bengal during 1910 was due to the prevalence of fever, cholera, and plague in some districts. The town of Jamalpur had a death-rate of 62·82 per 1000, 41 per 1000 being due to these three diseases. Monghyr lost 60·53 per 1000, the deaths from plague amounting to the very high proportion of 28·51. Throughout the province generally the agricultural out-turn was satisfactory, food was cheap, and a further rise in the birth-rate may be expected. Cholera prevailed throughout the province in 1910, especially in Bihar, the death-rate from this cause being 3·21 for Bengal as a whole, and 9·15 for the district of Shahabad. Patna and Muzaffarpur suffered nearly as badly; deficiency of proper water-supply and fouling of surface wells are the principal causes. Treatment of the wells with permanganate of potash is getting to be adopted and appreciated. The death-rate from small-pox showed a great decrease, the mortality

being only 0·14 per 1000, compared with 0·52 for the preceding five-year average. There was, unfortunately, an increase in plague, which caused 46,584 deaths, or a mortality of 0·92 per 1000, compared with 0·23 in the previous year. This increase was chiefly due to a limited prevalence in the Tirhut and Patna divisions, the rest of the province suffering but slightly. Evacuation is stated to have been the most popular means of prevention, disinfection and rat destruction being also carried out. The heading of fevers accounts for more deaths than all other causes put together—namely, 20·42 out of a total mortality of 33·10; this was, however, the lowest ratio for many years past, and well below the quinquennial mean of 22·79. A special malarial committee has been constituted to deal with the problems connected with fever prevalence in the province, and a medical officer and assistant surgeon have been selected to make a particular study of the subject.

Sanitary works in the way of improved water-supplies and drainage schemes are being carried out as funds permit. It is very satisfactory to learn that septic tank installations have proved a success; it is stated that these sanitary appliances are extremely efficient and, speaking generally, very well looked after. This excellent result is, no doubt, largely due to the good work that has been done in this branch of sanitary science by Major W. W. Clemesha, I.M.S., the Sanitary Commissioner, who has made it his especial study, and who is to be congratulated on the issue of this, his first, annual report.

Plague in India.

The plague statistics for the whole of British India for the week ending Dec. 23rd last show 8643 seizures, resulting in 7189 deaths. The provincial figures were: Bombay, 1886 deaths; Madras, 261; Bengal, 329; the United Provinces, 1934; the Punjab, 37; Burma, 41; and the Central Provinces, 830. There were 317 fatal cases in Mysore, 1504 in Hyderabad, and 44 in Rajputana. No cases of plague occurred in Eastern Bengal, Assam, or the North-Western Frontier Province. For the week ending Dec. 30th there were 9932 seizures and 7903 deaths from plague in all India, of which Bombay returned 1816 deaths; Madras, 302; Bengal, 947; the United Provinces, 1798; the Punjab, 141; Burma, 31; the Central Provinces, 822; Central India, 312; Mysore, 299; Hyderabad, 1378; and Rajputana, 50. No cases occurred in Eastern Bengal, Assam, the North-Western Frontier Province, or Baluchistan.

St. John Ambulance Association at the Durbar.

His Majesty the King Emperor has been pleased to bestow his Coronation Durbar medal on Major R. J. Blackham, R.A.M.C., in recognition of special services at the Coronation Durbar at Delhi. Major Blackham was commandant of a Coronation Durbar Contingent of the St. John Ambulance Brigade, consisting of nearly one hundred of all ranks, which served at Delhi throughout the Durbar period—i.e., nearly a fortnight. The contingent was well equipped in every respect and had the following transport establishment—viz., 3 transport carts, 15 ambulance carts, 36 transport ponies, and 30 riding ponies, specially provided for the occasion by His Highness the Maharaja of Jaipur. The St. John men were officially recognised by the Durbar authorities and were attached to the Civil Ambulances, under the command of Colonel C. J. Bamber, C.V.O., I.M.S. They rendered valuable services to many hundreds of cases and were fortunate enough to be on the scene at the only two serious accidents which occurred in the immediate vicinity of Their Majesties. This is the first occasion on which voluntary ambulance workers have been officially employed in India.

Jan. 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Health of Queensland.

THE annual report of the Government statistician for Queensland states that the total population on Dec. 31st, 1910, was 599,131. The general prosperity of the past few years was reflected in the marriage-rate, which was the highest for 30 years. The recent State-aided immigration probably contributed to raise the rate. The birth-rate, 27·3, was satisfactory, and illegitimacy shows no increasing ratio, although Queensland and New South Wales show higher rates in this respect than the southern States. The infant mortality figure was the lowest on record. The deaths from phthisis totalled 308, and 75 per cent. of the victims had lived 20 years or over in Queensland. The most common cause of death was organic heart disease, and tuberculosis ranks fourth, the second place being occupied by cancer. The report shows clearly that the Queensland climate has nothing about it to preclude the well-being of a white population, and its mineral and pastoral resources are unbounded. Unquestionably it will be the treasure-house of the Australian continent when its millions of acres are populated.

Venereal Prophylaxis.

Practical measures for the limitation of spread of venereal disease in Victoria are slow in taking shape, although some stir was recently made by the press and the medical profession. An advisory committee was nominated to assist the Government in introducing legislation, but so far nothing has been forthcoming. It was recently announced that this committee had secured lock wards at the Alfred and the Women's Hospitals, but this is now denied. The Minister for Public Health recently stated that the Government were anxious and willing to do anything in reason and that the matter must not be allowed to drop.

State Purchase of Radium.

The acting State Premier of Victoria recently asked the President of the Victoria Branch of the British Medical Association to report upon the advisability of a State purchase of radium, for use either at hospitals or on loan. An expression of opinion was asked from the honorary staffs of the Melbourne, St. Vincent's, Alfred, Women's, Children's, and Eye and Ear hospitals, and they have, through representatives, signed a joint report. In this they point out that radium is still on trial, and that so far as is known its curative power has not been established in any deep-seated disease. It is stated that certain superficial skin affections are curable by radium and that some forms of epithelioma have apparently been cured. The report advises against any large purchase of radium, but suggests that comparatively small amounts (worth, say £1000) might be kept at one or more hospitals for special cases. The report considers that the establishment of a radium bank for loan of specimens would be a great mistake and open to grave abuses.

Weather in Victoria.

The present year in Melbourne is the wettest on record. The rainfall to date (Dec. 23rd) is 37 inches, which is nearly double the average. The total in 1908 over the same period was 17·8 inches. The highest figures are 40 inches recorded in 1840, but there is some question of their accuracy. No particular detriment to the public health is so far observable as a result of the heavy rainfall.

Medical Practitioners Bill.

The medical profession of Queensland are at variance with the Government over some new legislation affecting the registration of medical men in that State. The Government insists on including provisions for registering herbalists and hydropathists, and recognising opticians. The members of the Queensland Medical Board have stated that if the Bill is passed in its present form they will at once resign their positions. One very remarkable clause in the Bill is as follows:—

> But no person shall be deemed to practise medicine or surgery who attempts or endeavours to cure or heal the sick or to restore others to health by prayers, faith, or religious methods, or by mental treatment, provided that no drug, medicine, or instrument is thereby prescribed or used whether directly or indirectly or whether internally or externally.

Health Act.

The Queensland Government has introduced a Bill giving much wider powers to the Board of Public Health and providing for the registration of nurses by the State.

Complimentary Dinner.

A complimentary dinner was tendered to Dr. F. Antill Pockley by a number of colleagues on Nov. 30th at the University Club, Sydney. The chair was taken by Sir Philip Sydney Jones, and the occasion was to mark the appreciation of the manner in which Dr. Pockley had directed the affairs

of the Ninth Australasian Medical Congress in his capacity of President.

Personal Items.

Dr. J. F. Wilkinson has been elected President of the Victorian Branch of the British Medical Association for 1912.—Dr. Judah Iona, who is an assistant demonstrator of physiology in the University of Melbourne, has been awarded a research scholarship of £250 for three years at the London University for his work on the toxins of puerperal infection. Dr. Iona has done some original work on the effect of adrenalin in delaying the action of certain poisons.—Professor H. B. Allen, dean of the faculty of medicine in Melbourne University, will leave for London early in January and will be absent for a year.

Dec. 27th, 1911.

Obituary.

JAMES SNOWDEN-SMITH, L.R.C.P. & L.M. EDIN., M.R.C.S. ENG.

HONORARY SURGEON TO THE TAVISTOCK (DEVON) COTTAGE HOSPITAL.

Mr. J. Snowden-Smith died suddenly on Jan. 30th, from syncope, whilst going over Portland Convict Prison with Captain Johnstone, deputy-governor of the prison, with whom he was staying on a visit for the benefit of his health. The deceased, who was 57 years of age, received his medical education at Guy's Hospital, London, and qualified M.R.C.S. Eng. in 1880; the year following he was admitted L.R.C.P. of Edinburgh. After holding the post of house surgeon at the Salisbury General Infirmary, he went to Tavistock, succeeding to the practice of the late Mr. Gilbert Northey. He soon became very popular in Tavistock and had an extensive connexion. He was honorary surgeon to the local cottage hospital, certifying factory surgeon, district and workhouse medical officer, and public vaccinator. He was held in high esteem at Tavistock, where he had practised for over 20 years, and much sympathy is felt there for his widow, daughter, and son, Lieutenant Snowden-Smith, who has done good work as an army aviator. The funeral, which took place at Tavistock, was largely attended.

ALLEN ABRAHAM DUKE, M.D. EDIN., L.R.C.S. & L.M. EDIN., L.S.A. LOND.

THE death occurred at Southwick, Sussex, on Jan. 30th, of Dr. Allen Abraham Duke, who formerly was a well-known Brighton medical practitioner. Seventy-five years of age, he had resided practically in retirement at Southwick for some years. Studying at the University of Edinburgh, he took the L.R.C.S. and L.M. diplomas as far back as 1858, and that of L.S.A. in London in the same year. He became Doctor of Medicine of the University of Edinburgh in 1859. For some time he was a surgeon in the Peninsular and Oriental Steam Navigation Company's service, assistant surgeon at H.M. Convict Prison at Portsmouth, and surgeon at the North Surrey Schools, Anerley.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Max Salomon, of Berlin, whose labours in the cause of obtaining sea-coast hospitals for consumptive cases, together with his frequent publications on the question of combating tuberculosis, have done great service, especially to the German working classes. He was in early professional life a military surgeon and served in the Franco-German war. Afterwards he practised in Hamburg and later in Berlin. He was much interested in the history of medicine, and published some 40 years ago a "History of Glycosuria." His manual of "Special Internal Therapeutics," too, went through three editions, and was translated into Italian. He was 74 years of age.—Dr. Theodor Piderit, of Detmold, author of a well-known work on mimicry, practised for several years in Valparaiso, Chili, but after his return to Germany gave himself up to literary work and teaching. He was 86 years of age.—Dr. Don Jose Maria Esquerdo, an eminent Spanish alienist physician and politician. He was several times elected Member of Parliament for Madrid.

THE NATIONAL INSURANCE ACT.

OUR correspondents in Scotland, Ireland, and Newcastle detail the present position of affairs in their localities.

THE WELSH MEDICAL COUNCIL.

The proposal to form a Welsh Medical Committee or Council to organise and conduct future discussions as to medical benefit under the Insurance Act with the Welsh Commissioners has met with general approval in Wales. At a meeting of the South Wales and Monmouthshire Branch of the British Medical Association on Feb. 2nd a resolution was unanimously passed in favour of constituting for Wales and Monmouthshire a Welsh Medical Council representing both members and non-members of the Association for the purpose indicated. It was further resolved that no offer from the Welsh Commissioners should be accepted until after the Representative meeting of the British Medical Association in London on Feb. 20th and 21st. In consequence of the approval with which the proposal has been received it has been resolved to postpone the meeting at Shrewsbury arranged for Friday, Feb. 9th, until Thursday, Feb. 15th, so as to allow time for the divisions in Wales and Monmouthshire to meet to discuss the resolutions it is proposed to submit to the Shrewsbury meeting, and to elect delegates to attend it. It has been suggested to officers of divisions that eligible non-members should be invited to the division meetings so as to ensure unanimity in the profession throughout Wales and Monmouthshire. The resolutions to be submitted to the Shrewsbury meeting, which will assemble at the Raven Hotel in that city at 2 P.M. on Thursday next, Feb. 15th, will include the reaffirmation of the six cardinal principles, and the appointment of a Welsh Medical Committee or Council to convey to the Board of Insurance Commissioners in Wales the decisions of the medical profession. The postponement of the Shrewsbury meeting has been rendered possible by the very general approval of the course proposed to be taken, which has done away with the necessity of holding the suggested preliminary meeting on Feb. 9th. The meeting on Feb. 15th will, it is anticipated, be able at once to proceed to the constitution of the Committee for Wales and Monmouthshire, and the election of an Executive Committee.

THE REFORM COMMITTEE'S PROPOSAL FOR AN AMENDING ACT.

Mr. Percy C. Raiment, honorary secretary of the British Medical Association Reform Committee, has forwarded to us the following copy of the principal headings of the Bill to Amend the National Insurance Act, 1911, which is being prepared by counsel for that committee. He wishes it to be understood that the points given only embody the barest outlines of the Reform Committee's proposals, and are necessarily incomplete as to details. The broad principles underlying the "Six Point Programme" have been loyally adhered to.

Principal Headings of Proposed Bill to Amend the National Insurance Act, 1911, now in preparation by the British Medical Association Reform Committee.

1. No person with income exceeding £104 per annum to be entitled to medical benefit under the Act.
2. No person with income not exceeding £65 per annum to be excluded from medical benefit under the Act.
3. Local Medical Committees to be constituted in every administrative area with administrative powers.
4. The Local Medical Committee instead of the Insurance Committee to be the authority under Section 15 (3) for fixing and varying the income limit within the above-mentioned amounts.
5. Statutory minimum capitation fee of 10*s.* per insured person per annum, or at the option of the Local Medical Committee, an equivalent minimum payment per visit and consultation.
6. The representatives of medical practitioners to be elected under Section 59 (2) (*c*) of the Act to be not less than one-sixth of the whole number of members of each Insurance Committee.
7. No person suffering from any injury or disease in respect of which compensation or damages may be payable or recoverable under any statute or at common law or who is deprived of sick benefit for misconduct under Section 14 (4) of the Act to be entitled to medical benefit under the Act.
8. The General Medical Council to be substituted for the Insurance Commissioners for the purpose of removing a medical practitioner from the panel under Section 15 (2) (*b*) of the Act.

THE NATIONAL MEDICAL UNION.

The executive of the National Medical Union met in Manchester on Feb. 6th to discuss the Insurance Act, and passed four resolutions, copies of which have been forwarded to each division of the British Medical Association.

The first was a vote of censure on the Council of the Association and a demand for its resignation. The second was a refusal to accept the report of the Council, because it does not embody insistence upon the six cardinal points being guaranteed by statute. The third was a renewal of the pledge not to go on any panel or medical committee until the six cardinal points are unreservedly conceded in such a manner that they cannot be altered or withdrawn in future, except by Act of Parliament. The fourth resolution recommended each division of the British Medical Association to instruct the Council not to enter into further negotiations with, or hold further interviews with, the Committee of the Insurance Commissioners. The various divisions of the Association are urged by the National Medical Union to support the above policy, and to instruct their Representatives to vote in accordance with it at the Representative meeting on Feb. 20th and 21st.

A SPECIAL MEETING OF THE CARDIFF MEDICAL SOCIETY.

A SPECIAL meeting of the Cardiff Medical Society was held on Tuesday, Jan. 16th, Mr. H. E. SKYRME, the President, being in the chair. There were considerably over 100 members and medical friends present.

The PRESIDENT, with a few remarks, introduced Dr. T. A. HELME, of Manchester, who gave his address. This consisted of a detailed justification of his own attitude towards the British Medical Association during the past 12 years. He refuted the charges of inconsistency and hostility to the Association which had been raised against him, and made a long and searching criticism of the policy pursued by the leaders of the Association in the matter of the National Insurance scheme. Dr. Helme retraced the course of the negotiations between the Executive of the Association and the Government, and condemned in detail the behaviour of the Council both towards the scheme and towards their constituencies. As Dr. E. J. Maclean, chairman of Representative meetings, was present, Dr. Helme felt at liberty to speak openly on these matters and to press home various damaging points in recent history. His concluding words were as follows: Now is the time to act. The National Insurance Act must be so amended as to secure the six cardinal points, either by an amending Act or possibly by regulations on the part of the Commissioners, regulations which shall secure unreservedly and permanently our cardinal points and which shall be alterable only by Act of Parliament or by regulations issued with the expressed consent of the profession. Our present position, then, is that we are dissatisfied with the weakness of the attitude of the officials of the British Medical Association, and we think the time has arrived for firmer and stronger action.

After a vote of thanks to the speaker, the following resolution was moved by Dr. W. MITCHELL STEVENS and seconded by Mr. E. TENISON COLLINS:—

That in the opinion of this meeting the National Insurance Act does not meet the just demands of the medical profession as formulated in the six cardinal points; that it is detrimental to the public interest; and that the situation thus created can only be adequately met by a refusal on the part of the profession to undertake any duties which the Act proposes to assign to its members.

Dr. MACLEAN then addressed the meeting. He avoided for the most part the personal indictment and allegations of Dr. Helme, confining himself to the broader aspects of the resolution before the meeting. He suggested that the proper tribunal for trying the issues raised by Dr. Helme was the forthcoming Representative meeting. He deplored the ventilation of such matters in such a manner as fatal to the interests of the profession. He strongly advised the meeting not to take up the line indicated by the resolution. The result of that course being followed would be that the regulations of the Commissioners would be formed irrespective of the policy of the profession. Dr. Maclean characterised this course as foolish, ridiculous, and mischievous, and insisted that the profession should band itself together to present its case to the Commissioners, the committees, and the public, and continue up to the point of refusing to form a panel unless its conditions were fulfilled.

An amendment was proposed by Dr. W. B. CRAWFORD TREASURE, seconded by Dr. LLEWELLYN, as follows:—

That the National Insurance Act does not meet the just demands of the medical profession as formulated in the six cardinal points of policy, and that in the opinion of this meeting no member of the profession shall undertake the treatment of insured persons until the six cardinal points have been conceded.

After Dr. W. E. THOMAS, Dr. T. H. MORRIS, Mr. W. J. GREER, Dr. MARTIN, and Dr. D. A. PATERSON had taken part in a discussion the amendment was put to the meeting and lost, and the original resolution was then carried. Only members of the society took part in the vote.

THE LONDON HOSPITALS AND THE ACT.

A meeting of chairmen of the metropolitan hospitals to which medical schools are affiliated, convened by Mr. Sydney Holland, took place on Friday, Feb. 2nd, when the conclusion was arrived at that for the present no change should be recommended in the admission of either in- or out-patients or in the supply of materials for treatment. It was resolved:—

That a committee be formed of the secretaries of the following hospitals:—The London, St. Bartholomew's, Guy's, St. Thomas's, the Middlesex, and the Seamen's (Greenwich), to collect information during the year and to report to a further meeting to be then held.

It is expected that the hospitals will come to some general agreement as to payments from insured patients or approved societies; and it was decided that steps should be taken to explain to subscribers that the Act did not propose to help patients needing serious operations, lengthy nursing, or special treatment, so that the claims on the voluntary hospitals would remain as great as before.

THE NATIONAL INSURANCE ACT AND THE MEDICAL PROFESSION.

A correspondent has sent us the following tabulated list of clauses in the Act affecting the medical profession:—

Section.	
1	Those entitled to insure.
Schedule 1, part 2 ...	Those not entitled to insure.
8 (1) (*a*)	Medical benefits, definition of.
14 (1) and 15...	,, ,, administration of.
15 (6) and 42 (*d*)	,, ,, original grants for.
15 (7)	,, ,, supplementary grants for.
15 (6) and 42 (*e*)	,, ,, administrative expenses of.
8 (8) (*a*)	,, ,, commencement of.
10 (1)	,, ,, suspension of.
Schedule 4, part 2 ...	,, ,, extension of.
8 (1) (*b*)	Sanatorium benefits, definition of.
16	,, ,, administration of.
16 (2) and 42 (*c*)	,, ,, original grants for.
61 (3) and 64 (1)	,, ,, supplementary grants for.
61 (2)	,, ,, administrative expenses of.
10 (1)	,, ,, suspension of.
17 (1)	,, ,, extension of.
14 (4)	Suspension from certain benefits because of misconduct.
37 (1) (*a*)	Additional benefits.
Schedule 4, Part 2.	
11	Compensation claims.
8 (1) (*c*)	Maternity benefits, definition of.
20	,, ,, re-insurance of.
18 (1)	,, ,, administration of.
18 (1)	,, ,, call on advice of midwife
19	,, ,, duty of husband.
46 (2) (*ii*)	State medical services (Naval, Marine, and Army).
46 (3) (*h*)...	State medical services, Sea Fishing Service.
48 (12)	Charitable medical service, contributions to hospitals.
12	(*a*) by insured persons.
21	(*b*) by approved societies.
21	(*c*) by insurance committees.
51	Charitable medical service, institutions and homes.
21	Charitable medical service, dispensaries.
60 (1) (*b*)	,, ,, ,, lectures on health.
21	Nurses for insured persons (district; specially appointed).
45 (1) (*d*)...	Aliens.
69 (1); 71	False declarations by insured persons.
57 (1); 80 (1); 81 (1); 82 (1); 83 (1)	Machinery for conduct of Act—Commissioners.
58	,, ,, ,, Advisory Committees.
59	,, ,, ,, Insurance Committees.
62	,, ,, ,, Local Health Committees.
65; 78	Amendment of Act.

Our correspondent has been officially engaged in working upon the Act, and his indication where to find particular things in a complicated document may be of service.

THE IMPERIAL MEDICAL REFORM UNION.

A special meeting of the council of the Imperial Medical Reform Union was held on Thursday, Feb. 1st, to consider an

invitation from the National Health Insurance Commissioners to appoint two delegates to attend the conference convened for Friday, Feb. 2nd. There was a full attendance of members, the president, Mr. M. C. Corner, being in the chair. Mr. George Brown, general secretary, said that he had just received a telegram from the National Health Insurance Joint Committee stating that the proposed conference had been postponed. He presumed that the postponement was due to the refusal of the Royal College of Physicians of London and other medical corporations to take part in the conference. Hence it would not be necessary to appoint delegates. The council could, however, if deemed desirable, nominate two delegates to represent the union should a conference be convened before the next ordinary meeting of the council. After some discussion it was unanimously resolved, on the motion of Dr. J. B. Cook, that at present no action be taken which might in any way be regarded as antagonistic to any other representative medical organisation.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians of London on Jan. 25th and of the Council of the Royal College of Surgeons of England on Feb. 1st Diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the undermentioned candidates, who have passed the Final Examination of the Conjoint Examining Board and have complied with the necessary by-laws:—

Thomas Stevens Allen, Guy's Hospital; Soliman Azmy, Cairo and University College Hospital; George Victor Bakewell, B.A. Cantab., Cambridge University and London Hospital; *Grantley Barratt, London Hospital; Dougan Bird, M.B., B.S. Melb., Melbourne University and St. Mary's Hospital; Claude Hebden Barker Booth, Cambridge University and London Hospital; Arthur Vincent Boyall, B.A. Cantab., Cambridge University and Charing Cross Hospital; Terence Campbell Butler, King's College and Westminster Hospital; Colin Guy Hirst Campbell, Cambridge University and Westminster Hospital; Arthur Barrett Cardew, Middlesex Hospital; Eric Edmund Chipp, St. Bartholomew's Hospital; Thomas Clarke, Leeds University; Hugh Gregan Crawford, Guy's Hospital; Campbell William de Morgan, St. Mary's Hospital; George de Swietochowski, M.D. Munich, Munich University and London Hospital; Edward Percy Drabble, London Hospital; Christopher Robson Dudgeon, King's College and Westminster Hospital; Norman Duggan, M.B., Ch.B. Manch., Manchester University and St. Bartholomew's Hospital; Philip Vanner Early, University College Hospital; Macormack Charles Farrell Easmon, St. Mary's Hospital; Wilfred Marlow Ecclestone, M.B. Toronto, Toronto University and University College Hospital; Gordon Ernest Dormer Ellis, St. Bartholomew's Hospital; Abel Evans, University College, Cardiff, and Charing Cross Hospital; Arthur Geoffrey Evans, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; David Benjamin Evans, University College, Cardiff, and St. Bartholomew's Hospital; George Arthur Ewart, B.A. Cantab., St. George's Hospital; Ibrahim Fahmy-Elminyawi, Cairo and University College Hospital; Montague Albert Farr, Charing Cross Hospital; Archibald Ferguson, St. Bartholomew's Hospital; Charles Michael Forster, B.A. Cantab., Cambridge University and Charing Cross Hospital; Andrew Alexander Fyffe, Sheffield University and University College Hospital; Alfred Linton Gardner, Guy's Hospital; George Herbert Garlick and John Torbet Smith Gibson, St. Mary's Hospital; Cyril Ernest Ambrose Goddard and Thomas Chivers Graves, M.R.C.V.S., B.Sc. Lond., University College Hospital; John Cecil Hallinan, Charing Cross Hospital; Ernest Ravensworth Hart, Guy's Hospital; Sidney Martin Hattersley, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Gordon Victor Hobbs, St. Mary's Hospital; Robert Hamer Hodges, King's College Hospital; Bernard Whitchurch Howell, St. Bartholomew's Hospital; Frederick James Humphrys, St. Thomas's Hospital; Reuben Levi Hurst, M.B. Toronto, Toronto University, University College and Middlesex Hospitals; Christopher Martin Ingoldby, London Hospital; Howel Gabriel Gwyn Jeffreys, B.A. Cantab., Cambridge University and St. George's Hospital; Nagubai Moreshwar Joshi, L.M.S. Bombay, Bombay University and Royal Free Hospital; Bhagat Ram Khanna, Punjab University and London Hospital; Leon Levene and Robert Henry Liscombe, University College Hospital; *Ernest Millington Livesey, M.B., Ch.B. Otago, Otago University; Andrew Carey McAllister, King's College Hospital; Maurice Mackenzie, London Hospital; Avenell Frederick Cleeve Martyn, St. Mary's Hospital; Philip Henry Mitchiner, St. Thomas's Hospital; Kavasji Cursetji Mulla-Feroze, L.M.S. Bombay, Bombay University and London Hospital; Francis Leslie Nash-Wortham, St. Bartholomew's Hospital; Percy Alfred Newton, M.B., Ch.B. Birm., Birmingham University; Burford Noel Norman, University College Hospital; William David Owen and Donovan Blaise Pascall, St. Bartholomew's Hospital; William Baly Peacock, L.D.S. Eng., King's College Hospital; George Harold Pearson, London Hospital; John Hawkes Pendered, B.A. Cantab., and Walter Sydney Perrin, M.A. Cantab., Cambridge University and London Hospital; Reginald Arthur Pittard, University College, Cardiff and London Hospital; John McFarlane William Pollard, Guy's Hospital; Herbert Barrett Pope, B.A. Cantab., Cambridge and Leeds Universities; George Lionel Preston, Guy's Hospital; Arthur Joseph Rae, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Peter Warwick Ransom, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Richard Bancroft Nevil Reade, St. Mary's Hospital; Evan David Richards, University College, Cardiff, and St. Bartholomew's Hospital; Edmund Uniacke Russell, King's College Hospital; Reginald Sherman, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Frederic Batttinson Smith, B.A. Cantab., Cambridge University and University College Hospital; Philip Smith, Guy's Hospital; Henry Kenneth Victor Soltau, St. Bartholomew's Hospital; Geoffrey Sparrow, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; James Lennox Stewart, Guy's Hospital; Claude William Treherne, St. Thomas's Hospital; Henri Rene Guillaume Van der Beken, London Hospital; Victor Vesselovsky, St. Thomas's Hospital; Ronald Herbert Vicary, Cambridge University and St. Mary's Hospital; Victor David Collins Wakeford, St. Bartholomew's Hospital; Lionel Charles Watkins-Baker, Bristol University; Arthur John Waugh, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Ernest White, L.D.S. Eng., Guy's Hospital and Sheffield University; Cyril Guy Whorlow, St. Thomas's Hospital; James Buckley Aquilla Wigmore, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Robert Waller Willcocks, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Winterbotham, B.A. Cantab., Cambridge University and University College Hospital; and Percy Arthur With, St. Bartholomew's Hospital.

* M.R.C.S. Diploma previously conferred.

Diplomas in Public Health were also conferred (in conjunction with the Royal College of Surgeons) upon the following 18 candidates:—

Arthur George Atkinson, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., St. George's Hospital; Robert Vickers Clayton, M.B., B.S. Durh., Durham University and Portsmouth Municipal College; Francis Gerrard Hamilton Cooke, L.R.C.P., M.R.C.S., L.S.A., University College; Maneckjee Merwanjee Cowasjee, L.R.C.P., M.R.C.S., Guy's Hospital and Royal Institute of Public Health; Frank Elton Cox, M.B., B.S. Melb., L.R.C.P., M.R.C.S., Melbourne University and St. Bartholomew's Hospital; George Henry Dupont, M.D., Ch.B. Edin., Edinburgh University and University College; Josephine Letitia Denny Fairfield, M.D., Ch.B. Edin., Edinburgh University and University College; William Miller Fairlie, M.B., Ch.B. Glasg., University College; William Robert Gibson, L.R.C.P., F.R.C.S., Guy's Hospital and King's College; John Andrew Hagerty, M.B., Ch.B. Glasg., Glasgow University; George Crichton Jackson, M.B., B.C. Cantab., L.S.A., Cambridge University, St. Mary's and St. George's Hospitals; Satyaranjan Maitra, L.M.S. Calcutta, Calcutta Medical College and Middlesex Hospital; Manmatha Nath Mitra, L.M.S. Punjab, Punjab University and University College; John George Owen, L.R.C.P., M.R.C.S., King's College; Henry Christian Ernest Quin, L.R.C.P. & S. Edin., L.F.P.S. Glasg., University College; Jessie Anne Scott, M.B., Ch.B. Edin., Edinburgh University and University College; Frederick Meadows Turner, M.D., B.C. Cantab., Cambridge University and Guy's Hospital; and Arthur Christopher Watkin, L.R.C.P., M.R.C.S., University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Licences in Dental Surgery have been conferred upon the following gentlemen, who have complied with the necessary by-laws:—

William Reginald Brandon, Manchester University; and Sidney William Ingram, Guy's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Albany:* Dr. Elting has been appointed Professor of Surgery.—*Indianapolis (Medical College of Indiana):* Dr. Willis D. Gatch, of Baltimore, has been appointed Professor of Surgery.—*Montreal (McGill University):* Dr. Donald T. MacTaggart has been appointed Professor of Forensic Medicine.—*Naples:* Dr. G. Severino has been recognised as *privat-docent* of Medical Pathology.—*Odessa:* Dr. Uskoff has been appointed Professor of Medical Pathology and Therapeutics.—*Palermo:* Dr. A. Zancia has been recognised as *privat-docent* of Otology and Laryngology.—*Pisa:* Dr. Marcantoni has been recognised as *privat-docent* of Medical Pathology.—*Prague (Bohemian University):* Dr. R. Kimler has been promoted to be Ordinary Professor of Pathological Anatomy.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on Jan. 26th at Caxton House, Westminster, with Sir Francis H. Champneys in the chair. The Board considered the following charges, amongst others, against the midwives whose names are given below, and ordered them to be struck off the Roll:—Mary Ann Carr, that while herself in a condition liable to be a source of infection, owing to a discharging whitlow on the thumb, she attended as a midwife at a confinement and delivered the patient of a child, contrary to the provisions of Rule E, 5. Ellen Gaskell, that being in attendance as a midwife at a confinement, the case being one of abortion, she did not explain that it was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband

or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 19. Ellen Gould, that being in attendance as a midwife at a confinement she failed to adopt the antiseptic precautions required by Rules E, 3 and 7, and having been sent for on account of the illness of the patient, and advising that a registered medical practitioner should be sent for. she did not hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 19. Elizabeth Hodgkinson, that being in attendance as a midwife at a confinement, the child's right eye being inflamed and discharging on August 13th, and the left eye being similarly affected on August 15th, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 20 (5). Ann Hole, that when attending to her patients she did not wear a clean dress of washable material as required by Rule E, 1, did not adopt antiseptic precautions, could not read a clinical thermometer, and that she did not keep a register of cases as required by Rule E, 23. Florence Matilda Magor, that being in attendance as a midwife at three successive confinements, the child in each case suffering from inflammation of, and discharge from, the eyes, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 19 (5) of the rules then in force. Margaret Morgan, that she was not cleanly in her person and house, as required by Rule E, 1, and that she did not comply with Rule E, 13, being unable to use a clinical thermometer. Marie Ozun, that on Sept. 11th, 1911, she was convicted at the Lowestoft petty sessions of feloniously stealing 31 canvas deck chair seats, and was thereupon sentenced to a fine of 4 guineas with costs, or in default one month's imprisonment. Emily Susannah Plumb, that being in attendance as a midwife at a confinement, the patient suffering from excessive bleeding, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 20 (3). Sarah Reed, that being in attendance as a midwife at a confinement, she did not adopt the antiseptic precautions required by Rules E, 3 and 7, and she did not take the patient's temperature at any time. The following midwives were censured after charges against them had been considered: Mary Jane Haines and Eliza Mercer. Grace Lingard and Mary O'Callaghan were cautioned after charges against them had been considered.

DONATIONS AND BEQUESTS.—The late Mr. Montague G. Jessett has left the residue of his property, after making certain bequests, to King Edward's Hospital Fund. It is expected that the residue will amount to about £40,000. The secretaries of King Edward's Hospital Fund have received an annual subscription of £5000 from Mr. Walter Morrison and £1000 from Mr. W. Waldorf Astor. —Several generous bequests to the Leicester Infirmary are announced. The principal one arises under the will of the late Mr. Alfred Adderly, J.P., of Woodhouse Grange, Leicester. After bequeathing several legacies and an annuity to his niece, Mr. Adderly bequeaths the whole of his estate to his wife for life, upon her death to his daughter for life, and subject thereto he bequeaths the whole upon trust for the Leicester General Infirmary. It is estimated that the infirmary may eventually receive a sum of about £80,000 under this bequest. Mr. Adderly was a life governor of the infirmary and a generous contributor to the fund for the reconstruction of the infirmary. A second legacy arises under the will of the late Mrs. Ellen Dyke Frost, whereby the infirmary has received £1000 for the general fund and £1000 for the children's hospital. A third bequest is under the will of the late Mr. Charles Turner, who died some four or five years ago, and from whose estate a sum of £1400 has already been received. The estate has now been finally wound up and a further sum of £933 8*s.* 1*d.* (being two-thirds of the residue) has been paid by the executors to the infirmary.

THE MORISON LECTURES OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—These lectures on Certain Aspects of Ataxia will be delivered by Dr. J. J. Graham Brown on Monday, Wednesday, and Friday, March 4th, 6th, and 8th, at 5 o'clock.

BRIGHTON WORKHOUSE AND AN OPERATING SURGEON.—The decision of the Brighton guardians to appoint a consulting and operating surgeon to the workhouse at an honorarium of 50 guineas per annum having been found distasteful to the local profession, the special committee dealing with the subject has expressed the opinion that the whole question of the medical organisation of the workhouse should be submitted to a thorough investigation with a view to secure the highest attainable standard of work. In order to obtain advice as to further proceedings, the committee is seeking an interview with the Local Government Board.

PRESENTATION TO DR. P. W. LATHAM.—It is proposed that a presentation be made to Dr. P. W. Latham by the medical men of Cambridge and district on his retirement from active work. He has for many years held a leading position as physician to Addenbrooke's Hospital, as Downing professor of medicine, and as a consultant for a very wide area. It is hoped that a meeting of subscribers may be convened to show the regard in which his fellow practitioners hold him. The honorary secretaries are Dr. J. Aldren Wright, honorary secretary of the Cambridge Medical Society, and Dr. H. Buckley Roderick, honorary secretary of the Cambridgeshire and Huntingdonshire Branch of the British Medical Association.

BOOKS, ETC., RECEIVED.

LARBERT, STIRLING DISTRICT ASYLUM.—Junior Assistant Medical Officer. Salary £130 per annum, with board, &c.

LEICESTER PARISH POOR-LAW INFIRMARY.—First Resident Assistant Medical Officer. Salary £140 per annum, with rations, apartments, and washing.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—Two House Physicians and Three House Surgeons, all for six months. Salaries at rate of £60 per annum, with residence and maintenance.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Physicians and Three House Surgeons, all for six months. Salary at rate of £60 per annum, with board and residence.

LIVERPOOL UNIVERSITY.—Obstetric Assistant. Salary £100 per annum, with residence.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Lecturer on Mental Diseases.

NEWCASTLE-UPON-TYNE UNION INFIRMARY AND WORKHOUSE.—Medical Superintendent. Salary at rate of £450 per annum.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, light, and fuel.

OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with quarters, board, and laundry.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—House Surgeon and Casualty House Surgeon, unmarried, each for six months. Salaries at rate of £80 per annum, with board, &c.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, &c.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Honorary Assistant Surgeon. Also Surgical Registrar. Salary £105 per annum.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Appointments.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Senior Resident Medical Officer, unmarried. Salary at rate of £100 per annum, with board, residence, and laundry.

SALFORD ROYAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £50 per annum, with board and residence.

SALISBURY, FISHERTON HOUSE.—Junior Assistant Medical Officer, unmarried. Salary £120 per annum, with board, apartments, &c.

SHEFFIELD UNIVERSITY.—Demonstrator in Experimental Physiology and Pharmacology. Salary £200 per annum.

STAFFORD, COTON HILL LUNATIC HOSPITAL.—Assistant Medical Officer. Salary £150 per annum, with residence, board, and laundry.

SOUTHAMPTON COUNTY BOROUGH.—Assistant Medical Officer of Health. Salary £250 per annum.

SOUTHAMPTON WORKHOUSE INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, washing, and attendance.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—House Surgeon. Salary £100 per annum, with apartments, board, and washing.

WALSALL AND DISTRICT HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Also House Physician. Salary £90 per annum, with board, residence, and laundry.

WEST AFRICAN MEDICAL STAFF.—Number of Appointments. Salary £400 per annum.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum.

WINDSOR, KING EDWARD VII HOSPITAL FOR WINDSOR, ETON, AND DISTRICT.—Senior House Surgeon. Salary £80 per annum, with residence, board, laundry, and attendance.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Bangor, in the county of Down; at Yarmouth, in the county of the Isle of Wight; at Tavistock, in the county of Devon; and at Oxted, in the county of Surrey.

Births, Marriages, and Deaths.

MARRIAGES.

BLACKMORE—MARTIN.—On Jan. 30th, at St. Marylebone Parish Church, Mr. H. Stuart Blackmore, R.A.M.C., to Norah, elder daughter of Dr. Sidney Martin.

DEATHS.

JACKSON.—On Feb. 4th, at 15, Huntingdon-street, Barnsbury, London, N., James Jackson, M.R.C.S., L.S.A., aged 70 years.

MACKINDER.—On Jan. 28th, at Hove, Draper Mackinder, M.D., F.R.C.S. Edin., aged 93 years.

PURKIS.—On Feb. 2nd, at Sekondi, West Africa, Dennis Woodley Purkis, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., in his 37th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN JAMAICA.

IN his report for 1910–11 on the Colony of Jamaica, the Governor, Sir Sydney Ollivier, K.C.M.G., states that the total population of the island, as shown by the census taken on April 2nd, 1911, was 831,383 (males, 397,439; females, 433,944). This is an increase of 30 per cent. over the figures of 20 years ago. The marriage-rate per 1000 continues to fall. The percentage of illegitimate births amounted to 62·4, as against 60·0 in 1909–10. The total births registered numbered 31,918, as against 32,402 in the previous year, the birth-rate being 38·6 per 1000 of estimated population, as against 39·7 in 1909–10. The deaths registered numbered 19,119, the rate per 1000 of estimated population being 23·1, as compared with 22·8 in 1909–10. Infantile mortality was accountable for 8871 deaths (46·3 per cent.) during the year. These figures represent deaths of children under five years of age, and of this number 7743 (or 40·4 per cent. of the total deaths) were those of children under two years of age. This is 24·36 per cent. of the number of births recorded for the year.

The total number of patients treated in the hospitals of the island during the year was 26,338, of whom 7542, or 28½ per cent., suffered from malarial fever. The total of deaths from malarial fever, malarial poisoning, and undistinguished fever was 3433, or 324 less than in 1909–10. There seems, therefore, some ground for the belief that the measures taken for the abatement of malaria are beginning to have effect, and that if they are steadily maintained, and filling and drainage works are undertaken from year to year, the mortality from this cause will rapidly decrease. An account of these measures was given in our columns on May 20th last year (p. 1370).

A vigorous campaign against yaws has been pursued as a result of the passing of Law 23 of 1910. The difficulties which are attendant on dealing with the matter are considerable, and different systems have been adopted in various West Indian islands. Much has been expected from a policy of compulsory segregation instituted in certain of the colonies, but it has not been attended with such success as might have been attained had the circumstances been more favourable. The initial expense of building asylums, and the recurring expenditure on maintenance of a large number of patients, usually created so great a financial strain that in some cases the attempt had either to be abandoned or the stringency of the segregation laws relaxed. Many of the people believed that the disease was inevitable, and that it was better for the children to contract it when young so as to become immune in later life, and it is said that they were directly exposed to contagion with that object in view. The confinement in asylums was, moreover, so distasteful to those who had contracted the disease that they frequently hid themselves and were screened from the authorities by their friends.

The system now in force in Jamaica is that of affording out-door treatment at the expense of the Government, and employing rural constables to discover and to report cases occurring in their districts, to persuade them to present themselves for treatment, and to return to the medical officer and continue doing so until cured. The reports received from the various district medical officers are, on the whole, very encouraging. In some districts there is a considerable decrease in the number of cases and a breaking down of the prejudice against medical treatment, as well as an increased willingness to present themselves voluntarily. The number of cases treated in 1910–11 was 7313, and in 1909–10 4555. The district medical officer at Port Antonio, Dr. C. A. Moseley, specially brings to notice the very satisfactory results obtained by him in the treatment of certain cases of yaws with the remedy known as "606." He used this remedy in four cases of several years' standing, and in each case the persons treated have to all outward appearances entirely recovered from the disease, and are now practically well. He recommends that the drug should be supplied to every hospital for the treatment of this disease, with a view to its being given a further trial.

The surgeon of the General Penitentiary called attention to the large percentage of prisoners admitted into the institution who were found to be suffering from hookworm disease, and stated that as a result of examinations it was shown that out of 71 persons admitted 51, or over 70 per cent., were found to harbour the worm. Reports from several district medical officers go to show that the disease is much more prevalent than has generally been supposed, not only among the East Indians, but also among the native population, and that many cases which might be attributed to malaria will in future be found to be due to hookworm. 50 per cent. of the prisoners admitted into the St. Catherine District Prison are reported to harbour the worm.

One of the points brought to notice by the commission which was appointed to report on the distress in certain portions of the parishes of Manchester and St. Elizabeth in 1909 was that the prevalence of syphilis was a cause of much suffering and inefficiency, and a vote was taken to enable the disease to be dealt with in these districts. As a result 346 cases have been treated at Government expense.

During the year it was decided to undertake an investigation into the causes of the mysterious malady locally known by the generic title of "vomiting sickness," which breaks out in certain districts in the cold season amongst the poorer classes, and, while maintaining a constancy of general characteristics, has hitherto displayed, when subjected to specific examination, a similitude to various forms of vegetable poisoning, to the effect of worms, meningitis, bronchitis, gastritis, and other more familiar diseases. Identified by one district medical officer as the result of poison, it has been speedily proved by another to be due to worms, and as quickly passed on by another as meningitis, and so on through the category. The Secretary of State, on being applied to, appointed, on the advice of the Tropical Diseases Research Committee, Captain T. J. Potter, R.A.M.C., to conduct the investigation. Captain Potter's report has not yet been received. With the view also of tracing the means by which enteric fever is disseminated, a committee has been appointed, consisting of Dr. A. G. Macdonald, the health officer of Kingston, where the greatest number of cases in any one locality in the island occur, and Mr. R. S. Turton, of Stony Hill, St. Andrew.

"CONSULTANTS."

To the Editor of THE LANCET.

SIR,—For the last 35 years I have worked as a general practitioner in a town about two hours' journey from London. Some of my patients when they are in town take the opportunity of going to see some "consulting" physician or surgeon about their health. The great man sees them, not in consultation with me, but by himself; and says to the patient: "Ah, I know Dr. X in your town. I will write to him and tell him what I think of your case, and will ask him to call on you and take charge of you." So the patient returns home and sends for Dr. X, and I never see the patient again, though I may have attended him or her and the family for many years. This sort of thing is frequently happening.

My object in writing to you is to ask why these great men in Harley-street, F.R.C.P. or F.R.C.S., are looked up to by general practitioners with honour and respect for behaving in a way which would stamp a general practitioner as a cad and a blackguard? Are good manners and professional courtesy to be reserved only for general practitioners?

I am, Sir, yours faithfully,

Jan. 31st, 1912. G.P.

*** The conduct described by "G.P." is universally condemned. Consultants would welcome the exposure of the offenders.—ED. L.

SOUTHWARK GUARDIANS AND THE DISSECTION QUESTION.

THE Southwark board of guardians, at their meeting on Thursday, Jan. 25th, were asked by Mr. F. G. Parsons, secretary to the Anatomical Committee, St. Thomas's Hospital, to reconsider their decision to refuse to allow unclaimed bodies to be sent to the London schools of anatomy. Mr. Parsons, in a letter addressed to the chairman, wrote as follows: "I am writing in the hope that you, as chairman, will be broad-minded enough to look on both sides of this question, and realise how absolutely impossible it is to turn out doctors fitted to operate upon and attend the sick (poor as well as rich) without being able to study the body and to practise the operations. I can assure you that the state of affairs is really very grave at St. Bartholomew's Hospital. They are starting their session with only one body. Here at St. Thomas's I have only three, and the other schools are in the same plight. The action of the Southwark guardians has been the most serious blow which medical education has received for several years, because it represents such a large and important union. I do wish you would come and see for yourself how carefully we treat the bodies committed to our charge, and let me bring you into touch with some of our leading medical men, from whom you may get any information you desire. Other guardians have done this and have gone away fully satisfied." Mr. C. W. Matkin, vice-chairman, inquired whether the St. Thomas's school of anatomy was dependent solely on the Southwark Union for bodies. The chairman, Mr. W. Savage, replied that he was unable to say. Mr. G. Hills, in proposing that the board adhere to the previous resolution not to allow any more bodies to be sent to the school of anatomy, said he was glad to learn that other boards of guardians, especially in the North of England, were following the example of the Southwark board of guardians. The resolution was carried without further discussion.

THE TYPEWRITING MACHINE IN MEDICINE.

IN a neat little pamphlet recently issued the Yost Typewriter Co., Limited, of 50, Holborn Viaduct, London, E.C., draw attention to the advantages of the typewriter to the medical man. The company has introduced machines specially adapted for the use of professional men in, for example, the writing of prescriptions and reports, records of diagnosis, and the preparation of articles for the press. The medical signs used in prescriptions are fitted to the Yost typewriter. A facsimile of a handwritten prescription, which is hard to beat for its illegibility, is illustrated, facing an elegant reproduction of it in the neat and clear typewriting of the Yost typewriter. Similar examples of elegant typewriting are given applied to making therapeutical records.

HEALTH MATTERS IN MAURITIUS.

ONE of the latest papers presented to Parliament before the prorogation in December was the report on the Mauritius 'Blue-book for the year 1910. From this it appears that the population of the colony (excluding the military and non-resident shipping population) is about 370,000, whilst the estimated population in the dependencies and outlying islands is 6289. The total number of births in the year was 13,338, giving a proportion of 35·7 infants born to 1000 persons living. The deaths registered numbered 12,488, giving a proportion of 33·4 deaths to 1000 persons living, the lowest since the year 1904. The birth-rate showed an increase of 1·4 per 1000 as compared with 1909, and the death-rate a decrease of 3·3 per 1000. The number of patients who were admitted to the public hospitals fell from 27,751 in 1908 to 23,205 in 1909, and 18,128 in 1910. The case mortality, however, showed a further rise, that for 1909 being 5·83 per cent., the highest recorded since 1906, and that for 1910 being 6·03 per cent., the highest since 1896. The number of deaths attributed to diseases classified as specific, febrile, or zymotic was 6369, or 51 per cent. of the total, of which 4593 were due to malarial diseases, 732 to diarrhœal diseases (dysentery 582 and diarrhœa 150), 385 to miasmic diseases, and 519 to bubonic plague. There were 1094 deaths from constitutional diseases, of which 105 were due to phthisis and 775 to tuberculosis, the figures for these two diseases in 1909 having been 182 and 809 respectively. There were 3382 deaths attributed to local diseases, of which 1522 were due to diseases of the respiratory system.

There was a severe outbreak of plague, the total number of cases being 731—a greater number than in any year since 1903, when 1395 cases were recorded. The first outbreak of plague occurred in 1899, when 1416 cases were registered. From 1903 onward each year, with the exception of 1906, showed a decrease in the number, and in 1908 there were only 167 cases. The following year showed a large increase, which was continued in 1910. In 1908 the cases were confined to Port Louis and the district of Plaines Wilhelms; in 1909 the outbreak spread to Pamplemousses, Rivière du Rempart, Moka, and Savanne; and in 1910 every district in the island was attacked. The disease assumed principally the bubonic form, 615 cases being of that type. There were 25 cases of pneumonic and 2 of septicæmic plague, all of which proved fatal. Of the total number of 731 cases, 553 proved fatal, giving a case mortality of 75·6 per cent. Gratuitous vaccination with Haffkine's antiplague vaccine was offered to the public and the fluid was issued free to those who applied for it; 1218 persons availed themselves of this means of protection, of whom one contracted the disease and died.

Malarial fever accounted for 2338 admissions to public hospitals, as compared with 3674 in 1906, 4272 in 1907, 5071 in 1908, and 3929 in 1909. The case mortality was 0·8 per cent., as compared with 0·91 per cent. in the previous year. The death-rate for malarial diseases fell to 12·3 per 1000 of the population, as compared with 14 per 1000 in 1909 and 15·5 per 1000 in 1908. Corresponding to the decrease in the number of malarial patients admitted to the hospitals, there was a decrease in the number of admissions for splenic hypertrophy, the figures being 1193 in 1908, 886 in 1909, and 561 in 1910.

In the Government and aided schools 12,724 children were examined for enlarged spleen, 24 per cent. of the children being found to be affected. The examination of children on the estates had not proved successful owing to the disinclination of the labourers to allow their children to be submitted to a spleen examination. The free distribution of quinine from depôts and at schools has been continued, the amount of the drug so distributed being 2151 lb. In April, 1910, malaria broke out in an epidemic form at La Dagotière and Valetta in the district of Moka, and a vigorous campaign was at once undertaken, in which ready assistance and coöperation was afforded by the proprietor of Valetta estate. The streams, canals, drains, and other places suited to the breeding of mosquitoes were cleared and cleaned, and quinine was distributed free by house-to-house visitation. As a result of these measures, the number of deaths at La Dagotière fell from 21 in the first half of the year to 6 in the second half, and at Valetta from 14 in the first half to 6 in the second half of the year. The number of children presented for vaccination at the public vaccine stations was 10,312, as compared with 9709 in 1909. Of this number 10,097 were successful.

THE "ALBAR" BREATHING APPARATUS.

WE have received from the Rev. Allan Barratt a little instrument, which he has invented for the purpose of expanding the alæ nasi and thus allowing the maximum quantity of air to reach the lungs through the nose. The instrument is made either of silver or of gold, and consists of a short length of stiff wire with a small forceps-like attachment hinged at each end. The forceps are fastened to the sides of the nose by means of a small screw, and the alæ are thus stretched apart. The apparatus is comfortable to wear, and is certainly in suitable cases an aid in overcoming mouth-breathing. An instrument of this kind might prove of use after operations for adenoids and polypus. The agents are the Albar Sales Company, 46, Holborn Viaduct, London, E.C., and the price of the instrument is 7*s.* 6*d.* in silver and £1 1*s.* in gold.

THE MINN-SLING.

Dr. G. V. Hewland has sent us for notice a new form of arm sling. The Minn-sling is really an adaptation of the triangular bandage made of a silk material, in black or colours. A broad piece of fabric is gathered at each end for the arm rest, and a band, with a buckle for adjustment, is attached to the gathered part and passed round the neck to suspend the sling. It is reversible, so that it can be used for either the right or the left arm, and is suitable for the whole limb, the forearm, or the hand. It seems to us that it should be light and comfortable to wear, while it grips the elbow quite firmly, and after the first adjustment the sling can be used again without alteration. The band can be worn under the coat collar, and there is no pressure on the neck from the buckle which comes at the side. We think the inventor can fairly claim that the Minn-sling possesses several advantages over the old handkerchief sling. It can be obtained in different sizes suitable from Messrs. Maw, Son, and Sons, of Aldersgate-street, London, E.C.

THE MODERN CATALOGUE OF THE MANUFACTURING CHEMIST.

THE advances made in pharmacy and pharmacology in recent years are well illustrated in the modern price list. It is, in fact, no longer a mere price list; it is very often a suggestive therapeutic guide. Apart from pure drugs and synthetic remedies there have now to be included the various metallo-organic preparations and those of organo-therapy. The call for control over the purity, constancy, and potency of modern remedies is urgent, and this is well illustrated in a general price list which has recently been issued by Messrs. Duncan, Flockhart, and Co., of South Canongate, Edinburgh, and 143, Farringdon-road, London, E.C. The list contains those standard drugs and combinations for which the firm is well known, and a section is devoted to the description of primary and secondary vaccines, tuberculins, and so forth.

"FOOD REFORM."

WE have received from the National Food Association, which numbers among its vice-presidents Sir Lauder Brunton, Professor Sims Woodhead, M.D., Professor Howard Marsh, F.R.C.S., and Professor Irving Fisher, of Yale, a copy of the new and revised edition of "Hints Towards Diet Reform," with 24 simple recipes. Copies can be obtained, price 2*d.*, or post free 3*d.*, from the secretary of the association, 178, St. Stephen's House, Victoria Embankment, London.

Enquirer would be glad if any reader of THE LANCET would inform him, through the medium of our columns, where he could find details regarding the technique of examination of the fæces for tubercle bacilli and deviation of complement in tuberculous individuals.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Feb. 13th–14th (London).—Central Poor-Law Conference.
March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—L. A. Dunn, James Berry): at 5.30 P.M.

Joint Meeting with the
MEDICAL SECTION and
SECTION OF ANÆSTHETICS.

Debate:

On a Paper by Mr. T. P. Dunhill of Melbourne: Partial Thyroidectomy under Local Anæsthesia, with Special Reference to Exophthalmic Goitre.

The Debate will be opened by Sir Victor Horsley, F.R.S. The following will take part in the Debate:—Mr. Charters Symonds, Mr. Leedham Green (Birmingham), Mr. Walter Edmunds, Mr. Wilfred Trotter, Mr. Lynn Thomas (Cardiff), Mr. Rupert Farrant, Dr. Hector Mackenzie, Dr. George Murray, Dr. Hale White, Dr. Herbert Scharlieb, Dr. Blumfeld, Dr. G. A. H. Barton, Dr. Albert Kocher (Berne), and Mr. James Berry.

The Debate will be continued on February 27th.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—J. H. Sequeira, Wilfrid Fox), at 11, Chandos-street, W.: at 5 P.M.

Demonstration of Cases.

NEUROLOGICAL SECTION (Hon. Secretaries—Wilfred Harris, T. Grainger Stewart): at 8.30 P.M.

Dr. W. Harris: Two Cases of Hæmato-rhachis, one Cured by Laminectomy after 18 months.

Dr. F. L. Golla: The Vestibule and the Perception of Space.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Sydney Scott, A. Logan Turner), at 11, Chandos-street, W.: at 5 P.M.

Dr. W. A. Milligan: (1) A Case of Severe Vertigo (Menière's Disease?), Operation, Recovery; (2) A Case of Suppurative Labyrinthitis Complicated with Suppurative Basal Meningitis, Operation, Trans-labyrinthine Drainage, Death, Post-mortem Records.

Mr. Hugh E. Jones: Three Cases of Operation on the Labyrinth for Vertigo (Non-suppurative).

Mr. Macleod Yearsley: Yankauer's New Speculum for the Direct Examination of the Naso-pharynx and Eustachian Tube.

Mr. George N. Biggs: Short Notes of a Very Severe Case of Streptococcal Infection of Both Ears.

Dr. P. Watson-Williams: Three Cases of Lateral Sinus Thrombosis.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—G. Harrison Orton, Cecil R. C. Lyster): at 8.30 P.M.

Papers:

Dr. F. Hernaman-Johnson: Secondary X-radiations, their Uses and Possibilities in Medicine.

Mr. William Hampson: A Method of Reducing Excessive Frequency of the Heart Beat by Means of Rhythmical Muscle Contractions Electrically Stimulated.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Dr. StClair Thomson: Cancer of the Larynx Treated by Larynx-fissure, with 80 per cent. of Lasting Cures.—Dr. W. H. Kelson: Aching Throat.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Prof. H. G. Greenish and Miss D. J. Bartlett: The Powdered Gentian, Nux Vomica, and Ipecacuanha of Commerce.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Council Meeting. 9 P.M., Dr. G. Lyon: The Cure of Consumption, a Review and a Forecast.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., Lieut.-Col. C. H. Melville, R.A.M.C.: Boots.—Mr. A. H. Tubby: Foot Deformities Acquired in Adult Life.—Lieut. Col. J. F. Donegan, R.A.M.C.: Demonstration of a Field Operating Table and of a Method of Attaching the First Field Dressing.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. A. M. H. Gray: Clinique (Skin). 5.15 P.M. Lecture:—Mr. C. H. Fagge: On the Selection for Operation of Fractures of the Long Bones.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. D. Forsyth: Coma and its Differential Diagnosis.

WEDNESDAY.—4 P.M., Mr. R. Milne (jun.): Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. J. McCann: Some Common Mistakes in the Diagnosis of the Diseases of Women.

THURSDAY.—4 P.M., Dr. E. Pritchard: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. L. Bunch: Some Tubercular Affections of the Skin.

FRIDAY.—4 P.M., Dr. J. G. French: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Edwards: Rectal Surgery.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Morton: The Principles and Applications of Radio-Therapeutics.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Delivered at the National Hospital for the Paralysed and Epileptic, Queen-square, on Feb. 6th, 1912,

BY FREDERICK E. BATTEN, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN FOR OUT-PATIENTS AT THE HOSPITAL, ETC.

GENTLEMEN,—The earlier experimental work on the transmission of poliomyelitis from man to monkeys is now so well known that it is not proposed in this lecture to refer to it in any detail, but the following brief summary of the facts of its transmission may well be mentioned.

EARLIER EXPERIMENTAL WORK.

In 1909 Landsteiner and Popper succeeded in transmitting poliomyelitis to two monkeys; they did not succeed in transmitting the disease to a series of monkeys. In the same year Knöpfelmacher produced the disease in a monkey by injecting into the peritoneum an emulsion of the spinal cord from a case of poliomyelitis. In the same year Strauss and Huntoon in America succeeded in producing poliomyelitis in a monkey by intraperitoneal injection.

Flexner and Lewis in 1910 produced the disease in monkeys by intracerebral injections, and were the first observers to transmit the disease through a series of monkeys. Landsteiner and Levaditi showed that the virus would pass through porcelain filters and also that glycerine did not destroy the virus. Working on the same lines and at the same time, Leiner and Wiesner in Vienna, Roemer and Joseph in Marburg, Krause and Meinicke confirmed these observations and added much to the knowledge of the nature of the virus.

NATURE OF THE VIRUS.

(*a*) *Filterability.*—It was shown by Flexner and Lewis, and Landsteiner and Levaditi that the virus would pass a porcelain filter. The latter observers noted that it would pass the Berkefeld, Chamberland, and Reichel filters, but that, after such a passage through the filter, the virus lost some of its virulence, and the incubation period was always prolonged, and the monkey either did not die or only died some days after the development of the disease.

(*b*) *Glycerine resistance.*—It has been shown by Landsteiner and Levaditi that the virus will resist the action of glycerine either concentrated or with 50 per cent. of water without impairing its virulence. The virus has been kept for 142 days in pure glycerine without affecting its virulence. In this respect the virus resembles that of rabies and vaccinia.

(*c*) *Resistance to drying.*—Flexner and Lewis, Landsteiner and Levaditi found that prolonged drying even to 24 days at a temperature of 22° C. did not diminish the virulence, and in this respect differed from rabies. Leiner and Wiesner, however, found that drying of thin films for four hours at a temperature of 37° C. did destroy the virulence. Leiner and Wiesner have shown that the virus is killed by exposure to a temperature of 55° C. for half an hour, and it is not killed by exposure to a temperature of −8° C.

(*d*) *Resistance to disinfectants.*—It has been shown by Landsteiner and Levaditi that 0·2 per cent. solution of potassium permanganate will kill the virus in one hour at a temperature of 39° C., and that 6 per cent. peroxide at the same temperature will destroy the virus in 45 minutes. The virus is not killed by ½ to 1½ per cent. of carbolic acid.

(*e*) *Cultivation of organism.*—The organism has not yet been cultivated, although Flexner and Lewis found some evidence that the organism multiplied in mixtures of broth and monkey serum.

The organism has not been stained or seen under the microscope, although Levaditi found a small round and oval corpuscle which he was able to stain by Löffler's method as modified by Borrel. Roemer made a similar observation, and examined them under the ultra-microscope.

THE RETENTION OF THE VIRUS IN THE ANIMAL BODY.

The question how long the virus remains in the body of the animal is difficult to answer. It has been found in the spinal cord 33 days after the onset of the disease. On the other hand, Leiner and Wiesner found that it had disappeared from the cord six days after the onset of the paralysis. In other parts of the body—viz., the nasal mucous membrane—it has been found six months after the onset (Osgood and Lucas).

PREPARATION OF EMULSION AND METHOD OF INFECTION.

The emulsion is prepared by pounding up 1 gramme of the infected portion of the spinal cord with 20 c.c. of normal saline solution; 0·5 c.c. of this emulsion is injected into the brain and 4–5 c.c. into the peritoneal cavity (Roemer).

The most certain method of producing infection is by injection of the virus into the brain. Injection into the peritoneal cavity, the anterior chamber of the eye, the subcutaneous tissue, and intravenous injections have all been successful in producing the disease.

Leiner and Wiesner showed that the virus could pass through the gastro-intestinal mucosa, but other observers, Levaditi and Landsteiner, failed to obtain positive results, and suggest that infection only takes place if there is a previous lesion of the intestinal walls. Leiner and Wiesner, in order to avoid the action of gastric juice, injected the virus into certain portions of the intestines after opening the abdomen. Three of the four monkeys thus operated on developed poliomyelitis. The fact that the virus can penetrate the mucous membrane of the digestive tract raises the possibility of the transmissibility of poliomyelitis by milk.

The virus will pass the nasal mucous membrane if injured (Landsteiner and Levaditi), but Leiner and Wiesner have shown that it will pass the uninjured mucous membrane. No case of natural contagion has been reported in a monkey, although infected and non-infected monkeys have been kept in close contact in the same cage.

MODE OF PROPAGATION OF VIRUS WITHIN THE BODY.

(*A*) *By the blood-stream.*—Injection into the blood-stream gives rise to poliomyelitis. This shows that the blood stream can carry the virus.

(*B*) *By the lymphatic system.*—Leiner and Wiesner produced poliomyelitis by injecting the inguinal glands with the virus. Flexner and Lewis injected a monkey subcutaneously with the virus. The animal was killed while suffering from poliomyelitis. From this monkey they then injected three monkeys: (1) with the spinal cord emulsion; (2) with the nodule formed at the place of injection; and (3) with the lymphatic gland corresponding with the inoculated region. Only the monkey that was injected with No. 2, the nodule, remained unaffected.

The virus has been obtained from the mesenteric glands of a child suffering with poliomyelitis (Flexner and Lewis). It has been shown (Flexner and Lewis, Levaditi and Landsteiner) that the virus injected into a peripheral nerve gives rise to paralysis, the disease commencing in the limb corresponding to the nerve injected.

Leiner and Wiesner found that if the nerve is divided immediately after the introduction of the virus into the peripheral end the spread of the disease is prevented. In whatever way the animal is infected, it is in the central nervous system, and especially the grey matter of the cord, that the virus tends to locate itself.

The disease cannot be transmitted by blood obtained from paralytic men and monkeys. This statement, though in the main true, is not absolutely so, for it has been shown by Flexner and Lewis—if large quantities, i.e., 25 c.c., are withdrawn from a monkey at the height of the disease, and are injected into a healthy monkey—that animal develops the disease. From human blood the disease has not been produced. The cerebro-spinal fluid also is free from the virus. In this connexion, however, Flexner and Lewis found that the cerebro-spinal fluid taken from a monkey three days after it had been given a cerebral injection and injected into a fresh monkey gave rise to poliomyelitis in six days. This shows that the virus can multiply in the cerebro-spinal fluid before the outbreak of paralytic symptoms.

INCUBATION PERIOD.

The incubation period is subject to very considerable variations. The variations depend upon (1) the *method of injection*, (2) the amount of virus given, and (3) the method of treating the virus before injection. Of 81 monkeys infected by Lewis and Flexner, 47 became paralysed between

the eighth and twelfth day, 18 became paralysed before the eighth day, and 16 after the twelfth day. Levaditi found the average incubation period from seven to ten days, and Roemer gives the incubation period as nine days.

The following factors were found to govern the incubation period. The less virulent the material, the longer was the incubation period. Filtration diminished the virulence (Levaditi and Landsteiner, Leiner and Wiesner). Thus an unfiltered emulsion produced poliomyelitis in seven days; the same quantity of filtered emulsion produced poliomyelitis in 27 days.

The quantity given also alters the incubation period. Dilution, again, has the same effect, and if diluted beyond a certain limit the virus will not produce poliomyelitis (Roemer). Thus an animal, injected intracerebrally with 0·5 c.c. of a 5 per cent. spinal cord emulsion, became paralysed on the seventh day and died on the eighth day. Another monkey, inoculated with the same quantity but ten times less concentrated, became ill on the twelfth and died on the thirteenth day. Another monkey, injected with the same quantity 100 times diluted, survived without having manifested any paralytic symptoms.

Leiner and Wiesner found that inoculation of a very concentrated virulent emulsion appeared to exercise rather an unfavourable influence on the development of poliomyelitis. The incubation period was slightly longer, and the course of the disease goes on as if in the nervous tissues there were, in addition to the acting virus, certain preventive substance which exercises a neutralising action on the virus.

WHAT HAPPENS DURING THE INCUBATION PERIOD?

Leiner and Wiesner showed that the virus spread to the nervous system before it was possible to observe any morbid manifestation in the central nervous system. Levaditi and Landsteiner found that the anatomical and pathological alterations commenced at a time very close to the outbreak of clinical signs. The virus of poliomyelitis can invade the nervous system and multiply there without causing for a time any apparent trouble or distinct lesion. The paralytic phenomena in a monkey may commence very suddenly—i.e., the monkey may be quite well in the morning and completely paralysed by the evening. It is a striking fact that in the majority of cases, in spite of the inoculation of the virus into the brain, the disease commences by paralysis localised to the lower extremities.

INFECTION OF ANIMALS OTHER THAN MONKEYS AND APES.

Most observers have failed to transmit the disease to animals other than monkeys and apes. Flexner and Lewis tried the horse, ox, pig, rat, cat, and rabbit. Levaditi and Landsteiner tried the rabbit, guinea-pig, young dog, and sheep. Leiner and Wiesner tried young dogs, fowls, pigeons, and rabbits; and Roemer rabbits, guinea-pigs, and mice. All without success.

Krause and Meinicke, Lentz and Huntemüller assert that they transmitted poliomyelitis regularly to rabbits. These rabbits succumbed with or without paralytic symptoms, and on histological examination the characteristic changes of poliomyelitis, more or less pronounced, were found. These investigators think that the inoculation into rabbits of cerebro-spinal fluid, blood, brain, or spleen obtained from human cases of poliomyelitis leads to the death of these animals, and the inoculation of similar tissues obtained from rabbits that have succumbed into other rabbits will bring about their death. When the injections were made into the blood and peritoneal cavity a greater number of positive results were made than when they were made into the brain. The effects could be produced in rabbits, not only with an emulsion of the organs mentioned, but also with Berkefeld filtrates prepared from them. Levaditi once succeeded in transmitting poliomyelitis in a rabbit, and the spinal lesion was even more marked than in a monkey.

Marks has further investigated this question. He used young rabbits; these were injected with an emulsion of the spinal cord from a poliomyelitic monkey—2·5–35 c.c. were injected intravenously and intraperitoneally. The injection had no immediate effect on the rabbit. Some of the animals injected died between the eighth and fifteenth day after injection. When death occurred the symptoms came on suddenly, the final stage being generally ushered in by convulsions and rigidity, and death took place in from 10 to 30 minutes after the onset of the symptoms. The post-mortem examination showed hyperæmia of the cortex, but no other striking lesion, and microscopical examination failed to show any further characteristic change. Other rabbits were injected with emulsions from various organs of the rabbits which died, and some of these rabbits succumbed. The virus was thus passed through a series of six rabbits. From rabbits in the second, fourth, and sixth set of the series of rabbits, monkeys were inoculated, and these monkeys all developed typical poliomyelitis.

These results leave no doubt that poliomyelitis can be propagated in certain individual rabbits, and also that the virus is not confined to the central nervous system, but occurs in equal amount in other organs. It is probable also that not all strains of the virus can be transmitted to even a small fraction of individual rabbits, and this may account for Roemer and Joseph's failure in a long series. It is thus established that the virus of poliomyelitis can survive and probably be propagated in domestic animals that do not show any of the symptoms of poliomyelitis as it occurs in man.

Roemer has observed in guinea-pigs a disease similar to poliomyelitis in man. It arose *spontaneously* in a guinea-pig, and was transmitted to a series of these animals by inoculation. All the animals were paralysed between the ninth and twenty-third day after injection. No organism was visible; the virus passed the Berkefeld filter and was well preserved in glycerine. The virus was present in the brain, spinal cord, liver, inguinal and prævertebral glands, but was not present in the blood, kidney, lungs, or urine. The cord showed the typical lesions of poliomyelitis.

IMMUNITY.

On clinical grounds there is good reason to believe that an individual who has survived an attack of poliomyelitis is immune to a second attack. Experimentally it has been shown by Flexner and Lewis, Levaditi and Landsteiner, and Roemer, that monkeys which have survived the acute period of infection are immune to a fresh dose of the virus. Roemer considers that immunity is only acquired after about the twenty-fourth day, but other observers do not confirm this observation.

In one case Leiner and Wiesner have been able to re-infect a monkey which was paralysed for 18 days. This is probably an exceptional instance. Leiner and Wiesner performed experiments to determine if the nervous system of monkeys, killed after the acute stage had passed and the refractory stage reached, contained an appreciable quantity of the active virus. They found that they could transmit the disease by using the spinal cord of a monkey killed on the twenty-fourth day of the disease. This would seem to show that the active virus and the antibodies can exist at the same time and in the same individual.

PRODUCTION OF ARTIFICIAL IMMUNITY.

Levaditi and Landsteiner used the same method for rendering a monkey immune against poliomyelitis as is used for producing immunity against rabies. To a certain extent this method was successful, but in some cases poliomyelitis has been produced by injection of the dried cords. Flexner and Lewis, by giving injections of diluted virus, were able to make monkeys immune to many times the lethal dose.

Flexner and Clark found the immunity principle to exist, both in the blood and cerebro-spinal fluid, soon after an attack of poliomyelitis. After one to two months the cerebro-spinal fluid lost its immunity principles, but it remained in the blood for years.

Hexamethylenamine given by the mouth delays, and may prevent, infection (Flexner and Clark). Kraus found that saline emulsion of brain and cord of a monkey, treated for five days with 1–1½ per cent. carbolic, is no longer infective on subcutaneous injection; 10 c.c. of virus thus sterilised, injected subcutaneously, protects animals against a subsequent subdural infection. Serum which is viricidal *in vitro* does not confer protection when injected subcutaneously.

SERUM DIAGNOSIS.

1. *Experimental method.*—Levaditi and Landsteiner, and Müller have shown that it is possible to test the serum of patients and monkeys for their viricidal properties. For this purpose a 5 per cent. emulsion of the spinal cord containing the active virus is mixed with an equal quantity of the serum to be tested. The mixture must be made at a temperature of 34° C., and stood at room temperature for several hours. It is then injected intracerebrally in quantities of 0·6–0·8 c.c.

into a normal monkey. A control monkey receives the same quantity of the virus. The control monkey becomes infected, the other monkey remains free. This experiment has been tried with the blood of patients who have had herpes zoster, but the experiments were inconclusive, as the control monkey was not affected (Müller).

Anderson and Frost found that the blood serum, in six out of nine suspected cases of abortive poliomyelitis, was viricidal against the virus of the poliomyelitis. Landsteiner, Levaditi, Leiner, and Wiesner have all shown that the serum is viricidal *in vitro*, but not *in vivo*. The serum injected into animals has no preventive or curative effect.

2. *Deviation of the complement method.* — This point has been investigated by Wollstein, Roemer, Joseph, Levaditi, and Landsteiner. All these observers agree that the use of an extract of organs containing the virus as antigen does not permit the discovery of antibodies in the serum or cerebro-spinal fluid.

"BREEDS" OF VIRUS.

It is essential before discussing "breeds" of viruses to understand how the words "breeds," "races," and "strains" should be used. The word "breed" is used to indicate a variation in character of the virus. The word "races" should be used in the same sense. Flexner and Clark have used the word "race" to indicate increased or decreased virulence of the virus as applied to monkeys and man. The word "strain" is used to indicate a variation in the source from which the virus is obtained.

Levaditi has brought forward evidence to show that there are differences between the viruses obtained from different sources. So far two breeds are known—the virus of Landsteiner, Vienna, and the virus of Flexner, America. Levaditi has shown that the virus of Flexner is neutralised *in vitro* by the serum of a monkey which has been rendered immune to the Flexner virus. It is not neutralised by the serum of a monkey rendered immune to the Landsteiner virus. On the other hand, the virus of Landsteiner is neutralised by the serum of a monkey rendered immune to the Landsteiner virus, but it is not neutralised by the serum from a monkey rendered immune to the Flexner virus.

The Flexner virus is more virulent than the Landsteiner virus. It remains to be proved if the English virus differs from the above two. No one in England has succeeded in transmitting the disease from an English strain to a monkey.

Flexner and Clark state that they have succeeded in implanting upon monkeys all the ten strains of human virus which they have examined. That is to say, monkeys have been infected from ten human cases. These authors state that other experimenters have only been able to implant about one half of the human strains of poliomyelitic virus upon monkeys. In order to succeed in all instances it is necessary to inoculate emulsions of the human spinal cord, and preferably to make double inoculation into the brain and peritoneal cavity.

The human strains of the virus not only infect monkeys less readily than do the modified or monkey strains, but the experimental disease produced by them is less severe and less fatal. After the strains have once become wholly adapted to the monkey the paralytic disease appears in a more severe form, and the degree of infectivity rises, so that exceedingly minute doses of a filtrate are capable of producing constant infection.

ELIMINATION OF THE VIRUS.

Levaditi and Landsteiner have found the virus in the salivary glands. It has not been found in the saliva. Flexner and Lewis have found the virus in the mucous membrane of the nose of a monkey killed during the acute stages of the disease. Osgood and Lucas have found it in this situation six months after the onset of the disease. Leiner and Wiesner showed that the nasal mucous membrane became infected on the second day after injection. The virus has not been found in the urine, fæces, kidney, or intestinal mucous membrane.

Flexner and Clark found the virus to be present in the tonsils and pharyngeal mucosa of a patient who had died during the acute stages of poliomyelitis. They obtained successful experimental results by preparing an emulsion of the tonsil with 0·5 per cent. solution of carbolic acid.

DISTRIBUTION OF THE VIRUS OUTSIDE THE BODY.

So far the only evidence upon this subject is that furnished by Neustaedter and Thro, who examined the dust in rooms in which cases of poliomyelitis had been nursed. After many failures they succeeded in producing poliomyelitis in a monkey with the filtrate of macerated dust in salt solution. They conclude, therefore, that poliomyelitis is propagated by dust, and that the naso-pharynx is probably the point of entry.

Flexner and Clark have shown that flies can harbour the virus in their bodies in a living and infective state for at least 48 hours.

TYPES OF EXPERIMENTAL POLIOMYELITIS.

All the usual types of poliomyelitis as seen in man have been reproduced experimentally in monkeys. There is the ordinary type with flaccid paralysis of one or more limbs, the ascending type, the cranial type, the abortive type. The "jumping" type has also been observed in monkeys, and Roemer gives the history of a monkey paralysed on the twelfth day which showed considerable amelioration at the end of the sixteenth day; but three weeks afterwards it had a relapse and died two days after being ill.

PATHOLOGICAL CHANGES FOUND IN EXPERIMENTAL POLIOMYELITIS.

The changes found in the brain and spinal cord in experimental poliomyelitis do not differ from those found in natural infection. In the spinal cord the lesions are usually more severe and widespread than in the brain. The meninges usually show a more or less diffuse infiltration with round cells. The layers immediately next to the white matter of the cord tend to show more cells than the layers next the dura mater.

The greatest accumulation of cells is about the arteries and veins, the sheaths of which are surrounded by cells. The effect of these cells on the lumina of the smaller vessels is considerable.

The meningeal cellular invasion is only interstitial, and does not give rise to an exudate upon the surface of the cord or brain such as occurs in acute exudative inflammation.

A NEW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting will be held at the Grand Hotel, Birmingham, on Tuesday next, Feb. 20th, at 5.30 P.M., to found an Obstetrical and Gynæcological Society embracing the Midland, Eastern, and Western Counties of Great Britain. The meeting will have the following agenda before it: (1) To consider the name of the proposed society; (2) to form rules and by-laws; (3) to arrange time and places of meetings; (4) to elect officers and council for 1912–13; (5) to dispose of such other business as may arise. At 7 P.M., after the meeting, a dinner will take place, the price of which, exclusive of wine, will be 7*s.* 6*d.* An early reply as to intention to be present or desire to join the society should be made to Mr. H. Beckwith Whitehouse, 52, Newhall-street, Birmingham), who is acting as honorary secretary (*pro tem.*) to the movement. A letter has already been circulated, signed by Dr. Edward Malins, Dr. Christopher Martin, Dr. Thomas Wilson, Dr. C. E. Purslow, Mr. Frederick Edge, Mr. J. Furneaux Jordan, Mr. Smallwood Savage, Dr. John T. Hewetson, Dr. Ann E. Clark, Dr. Mary D. Sturge, and Mr. Beckwith Whitehouse, these representative gynæcologists practising in Birmingham believing that the time has arrived for the formation of a new Obstetrical and Gynæcological Society embracing the Midland Counties, and, if sufficient support be obtained, including also the West of England and perhaps the East. To this letter many favourable replies have already been received.

SOME FORMS OF HÆMORRHAGE WHICH ARE DIFFICULT OF EXPLANATION.[1]

BY W. HALE WHITE, M.D. LOND. & DUB.,
SENIOR PHYSICIAN TO GUY'S HOSPITAL.

As I have been much interested in certain forms of hæmorrhage, I have taken this subject for consideration. Usually the explanation of the bleeding is easy—for example, an aneurysm ruptures, or tubercular ulceration eats into a vessel and the patient has hæmoptysis, or under the stress of a heightened blood pressure a diseased cerebral vessel gives way. It is not difficult to suggest why bleeding should follow an infarct, nor why when the vessels generally are greatly over-full it should occur in polycythæmia, nor why when they are locally over-full, as those of the portal area may be in cirrhosis, the patient should have hæmatemesis. It is easy to understand why, as the coagulation of the blood is greatly retarded in those who suffer from hæmophilia, minute injuries to vessel walls should lead to serious hæmorrhage.

When an occurrence is common we become so familiar with it that we are inclined to forget that we do not understand it. Rarely do we stop to reflect how extraordinary it is that if one ciliary muscle is paralysed as a result of diphtheria so is the other; if one anterior tibial nerve is inflamed by alcohol so will the other be. In the same way many varieties of hæmorrhage with which we are quite familiar may well cause much thought.

Let us first direct our attention to purpura. Here the bleeding is under our very eyes, and one thing is quite certain—namely, that the red cells cannot come through the walls of the vessels unless there is a solution of the continuity of those walls. No amount of talk about coagulation can explain hæmorrhage; deficient coagulation may explain why bleeding does not stop but not why it began; for it to begin there must be damage to the vessel walls sufficiently great to let blood corpuscles through. Purpura may occur as a result of giving a patient drugs—notably iodide of potassium, chlorate of potassium, and copaiba—by the mouth. It is difficult to resist the belief that these poisons, or derivatives from them, circulating in the blood lead to damage of the walls of the cutaneous vessels and consequent purpura. In the same way poisons or toxins circulating in the blood and causing local damage to minute vessels probably explain why septicæmia and some of the exanthemata are occasionally purpuric, although here it may possibly be that the micro-organisms themselves cause the bleeding either directly or by the formation of infarcts. Purpura is met with in scurvy, cirrhosis of the liver even if there is no jaundice, severe jaundice, and after the administration of serum, and in each instance it is extremely likely that there is some poison circulating in the blood which damages the minute vessels of the skin. Acute rheumatism, a common cause of purpura, is certainly a specific fever, and therefore the purpura may be toxic, as it may be in the exanthemata. Inasmuch as there must be a solution of vessel walls for the production of purpura, and several drugs cause purpura, we may assume that these drugs or their derivatives circulating in the blood act on the minute vessels so as to cause a solution of continuity and consequently hæmorrhage, and as no better explanation is forthcoming for purpuras—e.g., purpura hæmorrhagica and Henoch's purpura, in which there is no direct evidence of a toxin which damages vessels—we may, as here also there must be a solution of continuity of minute vessels, assume, without violent improbability, that in these varieties of purpura there are circulating in the blood toxins which can damage vessels in this way. It has been stated that the seat of the hæmorrhage in purpura is in the minute veins just at the point where they leave the subcutaneous tissue and enter the skin proper; they are especially weak at this point, hence when damaged they give way there.

In all purpura there must be a damage to vessels, and very often this damage extends to the vessels of other regions than the skin. Thus we have hæmorrhages into the gums and muscles in scurvy, gastro-intestinal hæmorrhages in Henoch's purpura, and epistaxis with internal hæmorrhage in many places in purpura hæmorrhagica, and internal hæmorrhages in jaundice. We have indication that some poisons damage some vessels more easily than others—for example, purpura is rare in scurvy, but hæmorrhages into the gums and muscles are common. In most cases of purpura hæmorrhagica bleeding takes place only into the skin; and in cantharides and turpentine poisoning, although the poisons must circulate in the blood to reach the kidneys, yet the damage to the vessels is usually confined to those of the kidney with consequent hæmaturia. When a poison circulating in the blood commonly selects some particular structure on which to act, we must assume that the chemical or physical nature of that structure is different from that of otherwise similar structures in such a way that the poison can produce results on it and not on them. For example, there must be some chemical or physical difference between the anterior tibial and musculo-spiral nerves, or else it could not be that if alcohol is going to cause neuritis it invariably picks out the anterior tibial most easily; on the other hand, if lead is going to cause a neuritis it almost invariably picks out the musculo-spiral before other nerves. In the same way there appear to be differences in the walls of the vessels in different parts, for some poisons circulating in the blood stream damage some vessels, and others damage others.

Having called attention to the fact that hæmorrhages under the skin may occur quite apart from any gross cause, that hæmorrhages inside the body may be associated with hæmorrhages into the skin, and that certain poisons act on particular vessels so as to cause them to rupture, let me now direct your thoughts to some mysterious internal hæmorrhages: by far the most remarkable is menstruation. The fundamental fact is that at stated periods the walls of the vessels of the uterine mucous membrane undergo some change which enables the blood to burst through. What this change is we do not know; some have spoken of it as a degeneration, but considering that the phenomena of menstruation and heat are normal it is doubtful whether degeneration is the right word; but at any rate in a few days the vessel wall undergoes an alteration which leads to a weakening, the blood ruptures into lacunæ in the uterine mucous membrane, and tearing through the epithelium passes into the uterine cavity. We know that the menstrual flow is controlled by a hormone secreted by the ovary, for excision of both ovaries is followed by a cessation of heat or menstruation, and there is considerable evidence that the transplantation of an ovary from another subject into one who has ceased to menstruate as a consequence of the loss of both ovaries will restore heat or menstruation. This function of the ovary is not derived from the corpus luteum, but it is not decided whether it is dependent upon the follicular epithelial cells or the interstitial cells. Formerly it was commonly believed that menstrual flow could take place from other organs than the uterus, and the belief has hardly died out. As recently as 1897 Oser stated that this might occur, and, indeed, it is admitted in a very recent text-book, but I think you will agree with me there is no real evidence in favour of vicarious menstruation, and therefore we must conclude that the substance secreted by the ovary which is carried by the blood to the uterus, where it causes such a change that the blood in the uterine vessels can rupture them, acts on the uterine vessels only, a fact which strongly suggests that the uterine vessels are different from other vessels, and which harmonises with the opinion expressed a few minutes ago that the most satisfactory explanation of some forms of pathological bleeding is to believe that it is caused by the circulation in the blood of toxins which act in particular on the walls of the vessels through which the blood ruptures.

I should now like to direct attention to some facts which support the belief that pathological hæmorrhage due to some substance circulating in the vessels and damaging the walls of the minute vessels may occur inside the body only. Everyone with even a moderate experience of work in the post-mortem room must be familiar with subpleural ecchymoses and those which occur in the alimentary tracts especially the stomach. Among 2246 post-mortem examinations I find them noted in 172, and of these 68 were performed upon those dead of an acute infective disease, such as pneumonia or pyæmia. In some instances these ecchymoses might be caused by obvious emboli, backward pressure, high blood pressure, or arterio-sclerosis, but a very large number remain in which no such explanation holds, and it is quite possible that some toxin damages minute vessels, but it may be that micro-organisms acting locally
